Table of contents

Volume 1

Executive Summary	xiii
ES.1 Background information on greenhouse gas inventories	xiii
ES.2 Summary of the national emissions and removal related trends	xiv
ES.3 Overview of source and sink category emissions estimates and trends	xvii
ES.4 Major inventory developments and recalculations	xxiii
Acknowledgements	xxiv
Part 1: Annual Inventory Submission	1
1. Introduction and inventory context	2
1.1 Background information on greenhouse gas inventories	2
1.2 National inventory arrangements	5
1.3 Inventory preparation and data collection, processing and storage	21
1.4 Brief general description of methodologies and data sources	24
1.5 Brief description of key source categories	31
1.6 General uncertainty evaluation	31
1.7 General assessment of completeness	32
2. Trends in emissions	34
2.1 Emission trends for aggregated greenhouse gas emissions	34
2.2 Emissions trends per capita and per GDP	36
2.3 Emissions trends by sector	37
2.4 Analysis of emissions trend drivers	39
2.5 Emissions trends for Kyoto Protocol – LULUCF inventory	43
3. Energy	45
3.1 Overview	45
3.2 Overview of source category description and methodology – energy	54
3.3 Source Category 1.A.1 Energy industries	63
3.4 Source Category 1.A.2 Manufacturing Industries and Construction	73
3.5 Source category 1.A.3 Transport	84
3.6 Source category 1.A.4 Other Sectors	102
3.7 Source Category 1.A.5 Other (Not Specified Elsewhere)	111
3.8 Source Category 1.b.1 Solid Fuels	113
3.9 Source Category 1.B.2 Oil and Natural Gas	138
3.10 Source Category 1.C Carbon Capture and Storage	165
Appendix 3.A Additional information on activity data	167

4. Industrial Processes and Product Use	191
4.1 Overview	191
4.2 Overview of source category description and methodology – Industrial Processes and Product Use	194
4.3 Source Category 2.A Mineral Industry	198
4.4 Source Category 2.B Chemical Industry	214
4.5 Source Category 2.C Metal Industry	228
4.6 Source Category 2.D Non-Energy Products from Fuels and Solvent Use	241
4.7 Source Category 2.E Electronics Industry	245
4.8 Source Category 2.F Product Uses as Substitutes for Ozone Depleting Substances	245
4.9 Source Category 2.G Other product manufacture and use	276
4.10 Source Category 2.H Other	290
Appendix 4.A Methodology applied to estimate uncertainty of CSIRO inverse modelled estimates of fluorinated gases (Category 2.F)	292
5. Agriculture	295
5.1 Overview	295
5.2 Overview of source category description and methodology – Agriculture	297
5.3 Source Category 3.A Enteric Fermentation	302
5.4 Source Category 3.B Manure Management	313
5.5 Source Category 3.C Rice Cultivation	336
5.6 Source Category 3.D Agricultural Soils	338
5.7 Source Category 3.E Prescribed Burning of Savannas	351
5.8 Source Category 3.F Field Burning of Agricultural Residues	351
5.9 Source Category 3.G Liming	354
5.10 Source Category 3.H Urea Application	355
Appendix 5.A Dairy cattle	357
Appendix 5.B Beef cattle	362
Appendix 5.C Feedlot cattle	372
Appendix 5.D Sheep	375
Appendix 5.E Swine	381
Appendix 5.F Poultry	387
Appendix 5.G Other livestock	391
Appendix 5.H Synthetic fertilisers	393
Appendix 5.I Crop and pasture attributes	397
Appendix 5.J Nitrogen leaching and runoff	401
Appendix 5.K Liming	402
Appendix 5.L Rice cultivation	403

List of Tables

Table ES.01	Net greenhouse gas emissions under the UNFCCC by sector, Australia (Mt CO ₂ -e)	xiv
Table ES.02	Net emissions by KP classification, Australia (Mt CO ₂ -e)	xv
Table ES.03	Emissions and removals associated with Articles 3.1, 3.3 and 3.4 of the Kyoto Protocol, Australia, 2013–2020 (Mt CO ₂ -e)	xvi
Table ES.04	Kyoto Protocol second commitment period final net position, Australia (t CO ₂ -e)	xvii
Table ES.05	Estimated recalculations for this submission compared with last year’s submission 1990, 2005, 2010–19	xxiv
Table 1.1	Reporting of national system characteristics against the guidelines for national systems (annex to decisions 19/CMP.1 and 3/CMP.11)	4
Table 1.2	Implementation of tier 1 quality control checks	14
Table 1.3	Results of reconciliation quality control objectives	15
Table 1.4	Expert reviews of methodologies and activity data	18
Table 1.5	Principal data sources for the estimation of Australia’s inventory	26
Table 1.6	Summary of data sources used to achieve completeness, where NGER data not sole source, by IPCC category	32
Table 2.1	National greenhouse gas emissions, Mt CO ₂ -e	34
Table 2.2	Emissions and removals associated with Articles 3.1, 3.3 and 3.4 of the Kyoto Protocol, 2013–2020	44
Table 3.1	Energy sector CO ₂ -e emissions, 2020	45
Table 3.2	Emission factors for CO ₂	58
Table 3.3	SO ₂ emission factors	60
Table 3.4	Relationship between IPCC source categories and ANZSIC sectors: Energy Industries	64
Table 3.5	Summary of methods and emission factors: Energy Industries	64
Table 3.6	Percentage of black coal and coke oven gas fuel mix in 1.A.1.c	69
Table 3.7	1.A.1 Energy Industries: recalculation of total CO ₂ -e emissions, 1990–2019	71
Table 3.8	Relationship between IPCC source categories and ANZSIC sectors: Manufacturing and Construction	73
Table 3.9	Summary of methods and emission factors: Manufacturing and Construction	74
Table 3.10	Feedstock assumptions in basic chemicals	78
Table 3.11	Product assumptions in basic chemicals	78
Table 3.12	Percentage of black coal and coke oven gas fuel mix in 1.A.2.a	79
Table 3.13	1.A.2 Manufacturing and Construction: recalculation of total CO ₂ -e emissions, 1990–2019	80
Table 3.14	Summary of methods and emission factors: Transport	85
Table 3.15	The Australian aircraft fleet, 2020, and emission factors by type of aircraft	87
Table 3.16	Weighted average emissions factors per Landing and Take Off cycle	88
Table 3.17	Aviation cruise emission factors (grams per tonne of fuel consumed)	88
Table 3.18	Aviation Tier 1 Non-CO ₂ Emission Factors	88
Table 3.19	Australian petrol passenger car exhaust emission standards, Australian heavy duty diesel exhaust emission standards	93
Table 3.20	Non-CO ₂ emission factors for non-road sources	96
Table 3.21	1.A.3 Transport: recalculation of total CO ₂ -e emissions, 1990–2019	99
Table 3.22	Relationship between IPCC source categories and ANZSIC sectors: Other Sectors	103
Table 3.23	Summary of methods and emission factors: 1.A.4 Other Sectors	103
Table 3.24	Residential biomass emission factors	108
Table 3.25	Non-CO ₂ emission factors for non-road mobile sources	108
Table 3.26	1.A.4 Other sectors: recalculation of total CO ₂ -e emissions, 1990–2019	109

Table 3.27	Summary of methods and emission factors: Other (Not Elsewhere Classified)	111
Table 3.28	1.A.5 Other: recalculation of total CO ₂ -e emissions (Gg), 1990–2019	112

Executive Summary

ES.1 Background information on greenhouse gas inventories

This is Australia's *National Inventory Report 2020*, submitted under the United Nations Framework Convention on Climate Change (UNFCCC) and the Kyoto Protocol (KP).

The Report contains national greenhouse gas emissions estimates for the period 1990–2020, and preliminary estimates for 2021. It has been prepared in accordance with the *Revision of the UNFCCC reporting guidelines on annual inventories for Parties included in Annex I to the Convention* agreed by the Conference of the Parties at its nineteenth session (decision 24/CP.19), and set out in document FCCC/CP/2013/10/Add.3¹, and the supplementary reporting requirements under Article 7 of the KP (decisions 6/CMP.9, 2/CMP.8, 2 and 4/CMP.7, 15/CMP.1, and 2, 3 and 4/CMP.11). Estimates for 1990–2020 will be internationally reviewed and finalised in accordance with UNFCCC and Kyoto Protocol processes.

The Report has been compiled using methods which conform to the international guidelines prepared by the Intergovernmental Panel on Climate Change (IPCC) and adopted by the UNFCCC – the *2006 IPCC Guidelines for National Greenhouse Gas Inventories* (IPCC 2006) and the *2013 Revised Supplementary Methods and Good Practice Guidance Arising from the Kyoto Protocol* (IPCC 2014). The methodologies used to estimate Australia's inventory have been improved over time and will continue to be refined as new information emerges, and as international practice evolves. In that context, the national method improvements in this Report include improvements informed by the *2019 Refinement to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories* (IPCC 2019), prepared by the IPCC and adopted at its 49th Session in May 2019. The IPCC 2019 and the *2013 Supplement to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories: Wetlands* (IPCC 2013 Wetlands Supplement) also informed the voluntary reporting of additional sources of *fugitive* emissions and certain sources in *wetlands* in this Report. The impact on greenhouse gas emissions estimates of refinements to methodologies adopted for this inventory has been summarised in section 4 of the Executive Summary.

The Report contains net emissions for 2020 compiled using reporting rules applicable to the KP second commitment period (CP2). 2020 is the eighth and final year of the KP CP2, which entered into force on 31 December 2020. Australia implemented its CP2 commitments prior to the Doha Amendment's entry into force, consistent with Decision 1/CMP.8. The Australian Government submitted its instrument of acceptance to the Doha Amendment on 9 November 2016.

The responsibility for Australia's greenhouse emissions reporting has been assigned to the Department of Industry, Science, Energy and Resources (the Department). The Department undertakes all aspects of activity data coordination, emissions estimation, quality control, preparation of reports and their submission to the UNFCCC on behalf of the Australian Government.

1 <http://unfccc.int/resource/docs/2013/cop19/eng/10a03.pdf#page=2>

In addition to this Report, the Department publishes a range of supporting emissions estimates that, together, constitute the Australian National Greenhouse Accounts, including:

- *Quarterly Updates of Australia's National Greenhouse Gas Inventory*, which provide a summary of Australia's national emissions, updated on a quarterly basis;
- *State and Territory Greenhouse Gas Inventories*; and
- the *National Inventory by Economic Sector*, comprising emissions estimates by economic sector rather than by IPCC sectors as in this Report.

These documents are available on the Department's website at <https://www.industry.gov.au/policies-and-initiatives/australias-climate-change-strategies/tracking-and-reporting-greenhouse-gas-emissions>. They provide additional information with respect to Australia's emissions on both a regional and industry basis.

ES.2 Summary of the national emissions and removal related trends

ES.2.1 Greenhouse gas inventory – UNFCCC classification system (Paris Agreement NDC)

Australia's total greenhouse gas emissions were 487.6 million tonnes (Mt) of carbon dioxide equivalent (CO₂-e) in 2020. Total emissions have decreased by 22.1 per cent (or -138.7 Mt CO₂-e) on net emissions recorded in 1990, and have decreased by 19.9 per cent (or -121.1 Mt CO₂-e) on 2005 levels.

This Report contains greenhouse gas emissions estimates for 1990, 2005, 2010, 2015, 2019 and 2020 on the basis of the UNFCCC classification system. That is, this Report includes emissions and removals from the energy, industrial processes and product use, agriculture, waste and the land use, land use change and forestry (LULUCF) sectors (Table ES.01).

Table ES.01 Net greenhouse gas emissions under the UNFCCC by sector, Australia (Mt CO₂-e)

UNFCCC classification sector and subsector	Emissions Mt CO ₂ -e						Per cent change 2005–2020
	1990	2005	2010	2015	2019	2020	
1 Energy (combustion + fugitive)	293.7	400.1	418.4	418.7	431.2	415.5	3.8
Stationary energy	195.5	278.9	288.2	279.0	278.8	272.4	-2.3
Transport	61.4	82.2	88.8	95.4	100.3	93.5	13.7
Fugitive emissions from fuel	36.8	39.0	41.4	44.3	52.0	49.6	27.4
Carbon capture and storage						0.01	n/a
2 Industrial processes and product use	25.9	30.7	34.1	31.1	33.4	32.7	6.6
3 Agriculture	84.9	79.8	69.8	73.6	69.8	67.8	-15.0
4 Land use, land use change and forestry	200.6	83.8	66.4	2.9	-40.4	-40.1	-147.9
6 Waste	21.1	14.3	14.6	11.6	11.9	11.7	-17.9
Total net emissions	626.3	608.6	603.2	537.8	505.8	487.6	-19.9

Under the Paris Agreement, the Australian Government committed to a quantified economy-wide nationally determined contribution (NDC) to reduce national emissions by between 26 and 28 per cent on 2005 levels by 2030, assessed on an emissions budget basis covering the period 2021–2030, and achieve net zero emissions by 2050. In its updated NDC submission to the UNFCCC of 28 October 2021², the Government advised that the estimates of emissions and removals used in accounting for the NDC will be those reported in the national inventory, according to UNFCCC classifications. The Government further indicated that the national inventory used to track progress towards the commitment would apply the natural disturbances provision in reporting net emissions from infrequent, extreme wildfires in temperate forests, which are beyond control despite the extensive efforts of emergency management organisations. On 24 May 2022, the Australian Prime Minister stated Australia would set a new target to reduce emissions by 43 per cent (on 2005 levels) by 2030.

These estimates, and preliminary estimates for 2021, are also presented in Annex 3, Volume 3 of this Report using the emissions metric adopted under the Paris Agreement – 100 year time horizon GWP values from the IPCC Fifth Assessment Report.

ES.2.2 Greenhouse gas emissions – Kyoto Protocol classification system (Cancun Agreement QEERT)

Under the UNFCCC Cancun Agreement, the Australian Government committed to a Quantified Economy-wide Emissions Reduction Target (QEERT) of -5 per cent on 2000 levels by 2020. 2020 is the final year of the QEERT commitment period. In its fourth Biennial Report³, the Australian Government indicated that it will report progress towards that commitment based on an emissions budget for the 2013–2020 period and using estimates of net emissions according to KP classifications.

To support Australia's QEERT, this Report contains greenhouse gas emissions estimates for 2000 and 2013 to 2020 on the basis of the KP classification system. That is, this Report includes emissions and removals from the *energy, industrial processes and product use, agriculture and waste* sectors and the following KP *LULUCF* sub-classifications: *deforestation, afforestation, reforestation, forest management, cropland management, grazing land management and revegetation*. On this basis, total net emissions were 500.5 Mt CO₂-e in 2020, which was 9.9 per cent lower than in 2000. This estimate, and the estimates for the entire QEERT commitment period 2013–2020, will be internationally reviewed and finalised in accordance with UNFCCC processes.

Table ES.02 Net emissions by KP classification, Australia (Mt CO₂-e)

KP Classification sector and subsector	Emissions Mt CO ₂ -e									Per cent change 2000–2020
	2000	2013	2014	2015	2016	2017	2018	2019	2020	
Energy	364.3	414.1	408.1	418.7	428.1	430.2	432.6	431.2	415.5	14.0
Industrial Processes and Product Use	26.1	30.2	30.1	31.1	31.2	31.8	32.6	33.4	32.7	25.3
Agriculture	82.3	76.0	76.4	73.6	72.6	76.6	75.1	69.8	67.8	-17.5

ES.2.3 Greenhouse gas emissions – Kyoto Protocol second commitment period

This Report contains net emissions estimates for 2020 compiled using reporting rules applicable to the KP CP2.

Under the KP accounting rules Parties must report net emissions from the *energy, industrial processes and product use, agriculture and waste sectors* and from the mandatory Article 3.3 KP LULUCF activities *afforestation and reforestation and deforestation*. Parties must also include, for the CP2, the mandatory Article 3.4 activity *forest management* in their reporting. In addition, Australia accounts for the voluntary Article 3.4 activities *cropland management, grazing land management and revegetation*. Australia does not account for *wetland drainage and rewetting* for the CP2.

As shown in Table ES.03, the total net emissions associated with the KP account were 553.8 Mt CO₂-e in 2020. When Removal Units (RMU) from LULUCF activities are added, net liabilities in 2020 were 472.7 Mt CO₂-e. Australia's net position at the end of the KP CP2 commitment period stands at a net surplus of 562,347,430 Kyoto units (Table ES.04), subject to 2022 annual expert review and subsequent true-up period review and compliance assessment processes. Further detail on the LULUCF activities is provided in Chapter 2, section 2.5 of Volume 1 and Chapter 11 of Volume 3. Information on holdings and transactions of Kyoto units in the calendar year 2021, is provided in Chapter 12 of Volume 3.

Table ES.03 Emissions and removals associated with Articles 3.1, 3.3 and 3.4 of the Kyoto Protocol, Australia, 2013–2020 (Mt CO₂-e)

Sector and subsector	Emissions Mt CO ₂ -e							
	2013	2014	2015	2016	2017	2018	2019	2020
Energy	414.1	408.1	418.7	428.1	430.2	432.6	431.2	415.5
IPPU	30.2	30.1	31.1	31.2	31.8	32.6	33.4	32.7
Agriculture	76.0	76.4	73.6	72.6	76.6	75.1	69.8	67.8
Waste	12.1	12.0	11.6	12.1	12.3	12.2	11.9	11.7
Deforestation ^(a)	38.6	42.2	33.4	32.8	31.9	34.6	25.7	26.1
National inventory emissions (1)	570.9	569.0	568.3	576.8	582.7	587.1	571.9	553.8
RMU credits generated by Article 3.3 and 3.4 activities								
Afforestation/reforestation ^(a)	-23.8	-24.2	-24.0	-26.8	-28.1	-19.9	-16.1	-17.0
Article 3.4 activities	-36.9	-29.7	-40.1	-63.2	-66.9	-63.7	-70.7	-64.1
Total RMU credits (2)^(b)	-60.6	-53.9	-64.2	-90.0	-95.0	-83.6	-86.9	-81.1
Kyoto Protocol Total (1 – 2)	510.2	515.0	504.1	486.8	487.8	503.5	485.0	472.7

- (a) Australia has elected to account for Article 3.3 activities on an annual basis, and Article 3.4 activities at the end of CP2.
- (b) Accounting quantity in accordance with decisions 2/CMP.7 and 3/CMP.11 and estimates for *Cropland Management and Grazing Management* were adjusted for the emissions reported under Forest Conversion in the UNFCCC in 1990 for conversions up to 31 December 1989, and recorded in the report used to calculate the assigned amount, in order to avoid double counting.

Table ES.04 Kyoto Protocol second commitment period final net position, Australia (t CO₂-e)

Kyoto units	t CO ₂ -e
CP2 Assigned Amount	4,511,619,826
CP2 RMUs (2013–2020)	615,223,544
CP2 CERs	6,720,688
CPI CERs	21,768,290
Total Kyoto units (1)	5,155,332,348
National inventory emissions 2013–2020	4,580,468,682
AAUs cancelled to acquit voluntary action	12,516,236
Total liabilities (2)	4,592,984,918
Net position (1) – (2)	562,347,430

ES.3 Overview of source and sink category emissions estimates and trends

ES.3.1 Greenhouse gas inventory – UNFCCC

The *energy* sector was the largest source of greenhouse gas emissions in 2020 comprising 85.2 per cent (415.5 Mt CO₂-e) of total net emissions. *Energy* emissions increased by 41.5 per cent between 1990 and 2020 and decreased by 3.6 per cent between 2019 and 2020.

For the *energy* subsectors in 2020:

- *stationary energy* was the main contributor to total net emissions (55.9 per cent of total net emissions), and decreased by 2.3 per cent between 2019 and 2020;
- *transport* emissions (19.2 per cent of total net emissions) decreased by 6.8 per cent between 2019 and 2020; and
- *fugitive emissions from fossil fuels* (10.2 per cent of total net emissions) decreased by 4.7 per cent between 2019 and 2020.

Industrial processes and product use made up 6.7 per cent (32.7 Mt CO₂-e) of total net emissions in 2020, increased 26.4 per cent between 1990 and 2020, and decreased by 2.0 per cent between 2019 and 2020.

Agriculture emissions made up 13.9 per cent (67.8 Mt CO₂-e) of total net emissions in 2020, decreased 20.1 per cent between 1990 and 2020, and decreased by 2.8 per cent between 2019 and 2020.

The *waste* sector contributed 2.4 per cent (11.7 Mt CO₂-e) of total net emissions in 2020, decreased 44.5 per cent between 1990 and 2020, and decreased by 1.2 per cent between 2019 and 2020.

The UNFCCC *LULUCF* sector was a net sink of 40.1 Mt CO₂-e in 2020, equivalent to -8.2 per cent of total net emissions (including LULUCF). Between 1990 and 2020 there was a decrease of 240.8 Mt CO₂-e and this sector changes from a net source to a net sink, and between 2019 and 2020 there was a 0.3 Mt CO₂-e reduction in the net sink from this sector.

The full time series of the national inventory, including for major sectors, is presented in Figure ES.01.

A full overview of emissions estimates by source and sink is given in Chapter 2. More detailed information on the emissions results for individual sectors has been reported in the introductions to Chapters 3–7.

Figure ES.01 Net greenhouse gas emissions under the UNFCCC, by sector, Australia, 1990–2020 (Mt CO₂-e)

Focus on land sector estimates

The land sector makes an important contribution to Australia’s emissions profile, and as a consequence is a particular focus of Australia’s continuous national inventory improvement cycle. Below is a brief summary of key highlights from the land sector included in this Report. For further detail, see Chapter 6, Volume 2.

Trends since 1990

Declining LULUCF emissions since 1990 have been driven by steady reductions in primary forest clearing, fostering native regeneration and establishment of new plantations. Together these trends have reversed declines in forest cover.

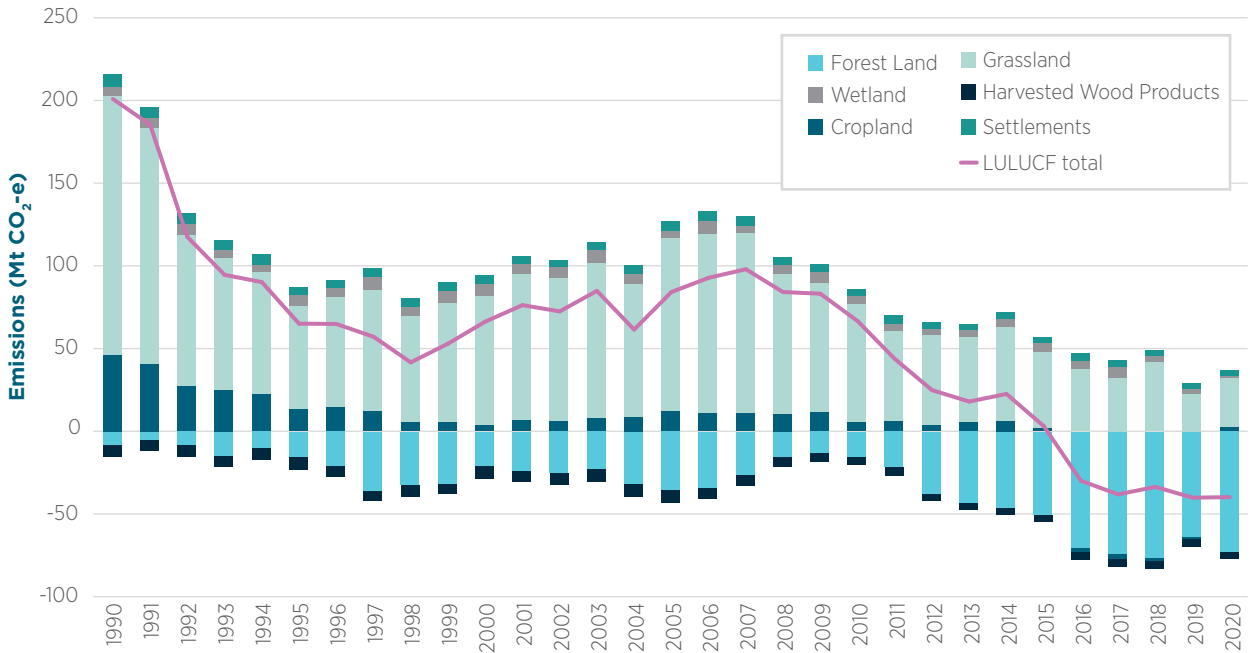

Reductions in native forest harvesting, increasing the sink from forest land remaining forest land, has also contributed to declining LULUCF emissions since 1990. Soil carbon emissions have reduced from 1990 levels, influenced by changes to cropping practices such as uptake of reduced tillage and stubble management.

Trends in 2020

Overall LULUCF emissions in 2020 remained stable, with a less than 1 per cent reduction in the total size of the net sink from the land (Figure ES.02) compared to 2019, reflecting the balance of increasing or decreasing trends in key sub-sectors.

Nevertheless, in 2020 Australia’s land sector was impacted by significant events: the breaking of the drought which, in some regions, was the worst on record, and a severe bushfire season affecting temperate regions, which is discussed below.

Figure ES.02 Total emissions from LULUCF, Australia, 1990–2020 (Mt CO₂-e)

Increasing forest cover

In Australia, the forest area increased by an estimated 0.1 million hectares (Mha) in 2020 and, cumulatively, has now increased by 2.4 Mha since 2005 (Figure ES.03).

Figure ES.03 Forest cover in Australia 1990 – 2020 (Mha)

Increased forest regrowth following the breaking of the drought in 2020 led to increasing sinks both within lands where clearing has been observed (since the start of the satellite record), and forest expansion through natural regeneration on grasslands.

Reductions in land clearing

The most important driver of net emissions from the land sector in 2020 has been the conversion of forest to other land uses⁴ including for agriculture, mining and settlements. The emissions from forest converted to other land uses totalled 38.2 Mt CO₂-e in 2020 (Figure ES.04: A+B+C).

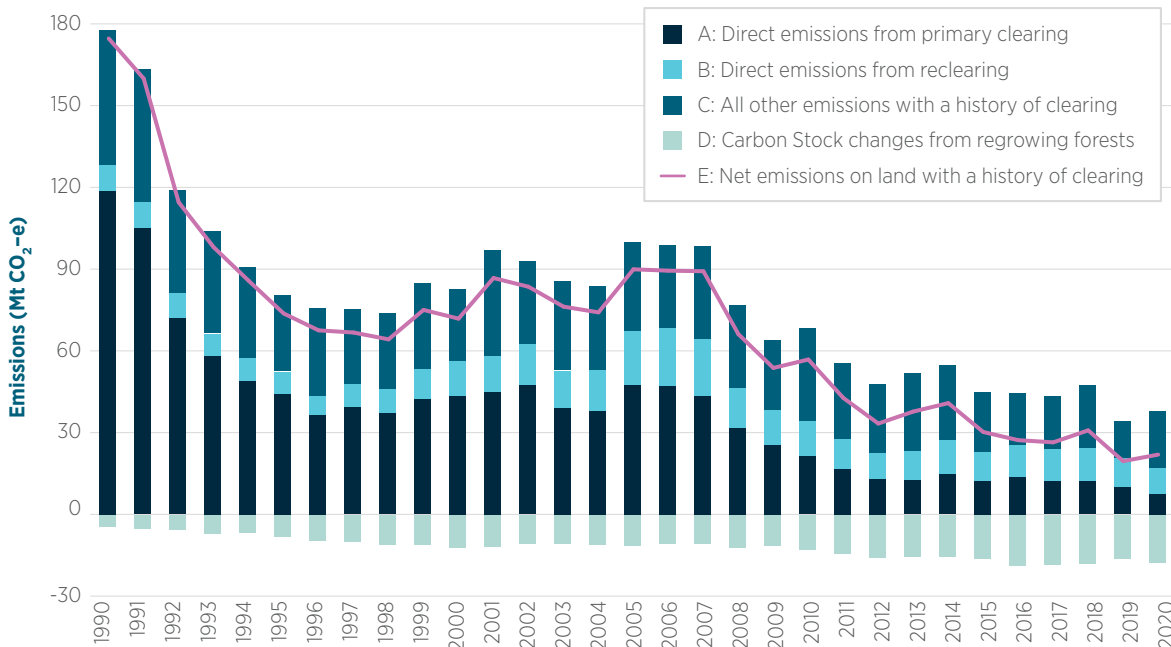

Direct emissions from primary forest clearing (from combustion of forest debris following a clearing event) fell in 2020 to 7.5 Mt CO₂-e, down 24 per cent from 2019 levels (9.9 Mt CO₂-e) (Figure ES.04: A).

Record-low re-clearing in 2020 followed slower rates of regrowth in preceding drought years (Figure ES.04: B). Direct emissions from re-clearing contribute far fewer net emissions per hectare than the clearing of mature forests on average due to the lower biomass of younger regrowth forests.

Sequestration from secondary regrowth on areas where previous land clearing has been observed (Figure ES.04: D) has been classified under *land converted to forest land*.

Despite declining rates of direct emissions from clearing, total net emissions from cleared land in 2020 show an increase over 2019 levels, reflecting high emissions from soil carbon from subsequent land uses (Figure ES.04: C) described below.

Figure ES.04 Land clearing direct emissions and ongoing emissions from subsequent land use, 1990–2020 (Mt CO₂-e)

⁴ *Forest converted to other land uses* includes the conversion of terrestrial native forests to grasslands, croplands, settlements and flooded lands as the elements of land clearing. The impacts of plantation removal and fire management in Northern Australia are calculated separately.

Severe wildfire season in temperate forests

In Australia, millions of hectares of bushland are burnt by wildfire each year (Figure ES.05). Most significantly, areas of tropical woodland – in Australia also known as savannas – are the largest areas of fire, where fires are frequent, of relatively low intensity, and the bush regrows relatively quickly.

The 2019–20 wildfires in Australia were unusual for the extent to which areas of temperate forests were burnt. Fires in these forests are relatively infrequent, are of greater intensity than the savanna fires, and generate large spikes in emissions followed by long periods of sequestration as the forests recover.

Australia's national inventory includes carbon emissions and post-fire sequestration associated with wildfires, based on satellite monitoring of fires across Australia and advanced carbon modelling of fire-prone ecosystems.

Consistent with international rules and international practice, this national inventory applies the concept of natural disturbances in reporting net emissions from infrequent, extreme wildfires in temperate forests, which are beyond control despite the extensive efforts of emergency management organisations.

In effect, consistent with the Managed Land Proxy, the national inventory includes the long-run trend in carbon stock change in the forests, reflecting the balance of the carbon lost in the fire and that reabsorbed by regrowth.

All states and territories containing temperate forests experienced natural disturbance conditions in 2020.

To ensure transparency, and consistent with Paris Agreement decision 18/CMA.1, national net emissions data – both with and without the natural disturbances provision – are reported in Table 2.1. As forests recover, reporting without the natural disturbances provision's application would reduce national emissions by 144 Mt CO₂ in 2021, and recovery from past disturbances is forecast to contribute a net sink of 701 Mt CO₂ over the decade to 2030.

The future recovery of the forest is expected to be complete, so the 2019–20 wildfires are expected to have a negligible impact on the long-run trend in carbon stock change in the affected forests.

The Department will actively monitor forest recovery from wildfires to ensure that future human disturbances, such as salvage logging, future fire disturbance and the impacts of changes in climate are taken into account.

As a result of the application of the natural disturbances provision, reported emissions and removals due to temperate wildfires in 2020 are dominated by the regrowth from previous years' fires, resulting in a net sink of 5.1 Mt CO₂-e in 2020.

Figure ES.05 Areas of wildfire in Australia, by forest and climate type, 1990–2020 (Mha)

Soil carbon emissions

Soil carbon emissions increased by 7.7 Mt CO₂-e in crop land and grazing lands in 2020. Increases were the result of a combination of climatic effects: low yields from winter crops in 2019 due to widespread drought conditions, reducing inputs to soil carbon; followed by a warm wet summer—conditions that increase decomposition of soil C (with limited crop cover to convert growing conditions to soil inputs) (Figure ES.06).

Figure ES.06 Emissions from soils in croplands remaining croplands and grasslands remaining grasslands, 1990–2020 (Mt CO₂-e)

ES.4 Major inventory developments and recalculations

ES.4.1 Implementation of IPCC 2013 Wetlands Supplement

Aspects of the IPCC 2013 Wetlands Supplement are being progressively implemented into the national inventory on a voluntary basis. Activity-based net emissions are provided for capital dredging affecting seagrass meadows, as well as for coastal aquaculture and emergence/loss of coastal wetlands that include tidal marsh and mangrove forest (reported under forest categories). A spatial model has been implemented for coastal wetlands to more accurately model establishment and clearing of mangroves. Estimates relating to wetlands categories are reported in Chapter 6 of Volume 2.

ES 4.2 Land Sector Model Improvements

Improvements to models used to determine land sector emissions have been made for:

- *Harvested native forests*: the Tier 3 method informed by spatial harvest data has been extended to public multiple use forest in the state of Tasmania, following adoption of this method for New South Wales and Victoria in the National Inventory Report 2019.
- *Savanna fire*: Research on carbon dynamics of live trees in the savanna regions of northern Australia has enabled the inclusion of live tree carbon pools for the tropical regions into Australia's estimates of fire emissions for the first time.
- *Plantations*: Major improvements have been made to the model for plantation species, including re-calibration derived from over 16,000 site-based observations of stand-level biomass.
- *Reservoirs*: Building on improvements from last submission, methane and CO₂ emissions from 201 Australian reservoirs representing 95% of national reservoir area, are more accurately estimated with a new approach, informed by remote sensing and depth gauge data, to reflect changes in surface area as reservoir levels vary through time.

Further details of methods and data sources are available in Chapter 6 of Volume 2.

ES.4.3 Carbon Capture and Storage

Fugitive emissions of greenhouse gases associated with the capture, transport, injection and long-term geological storage of greenhouse gases are estimated for the first time in this Report. The Gorgon LNG project (the first of its kind in Australia) commenced trials of the carbon dioxide underground injection system at the Gorgon natural gas facility in August 2019. Further details of methods and data sources are available in Chapter 3 of this report.

ES.4.4 Recalculations

The impact of the recalculations on emissions levels for the sectors including *LULUCF* was an increase in the estimate of total emissions for the year 1990 of 10.8 Mt CO₂-e and a decrease of 13.1 Mt CO₂-e in 2019 compared with last year's submission.

Recalculations for the land sector include the model improvements outlined above in section ES 4.2.

Other significant recalculations resulted from the introduction of estimation improvements for *oil and gas fugitives* and *solid fuels fugitives*.

Table ES.05 gives the estimated recalculations for this submission. Further information on recalculations is provided in each sector chapter and in Chapter 10 of Volume 2.

**Table ES.05 Estimated recalculations for this submission compared with last year's submission

PART 1

*Annual Inventory
Submission*

1. Introduction and inventory context

1.1 Background information on greenhouse gas inventories

1.1.1 Inventory reporting

The United Nations Framework Convention on Climate Change (UNFCCC) was ratified by Australia in 1992 and entered into force in March of 1994. One of the principal commitments made by the ratifying Parties under the Convention was to develop, publish and regularly update national emissions inventories of greenhouse gases.

Australia's *National Inventory Report 2020* (the Report) provides estimates of Australia's net greenhouse gas emissions for the period 1990–2020. This Report and associated common reporting format (CRF) tables are submitted to the UNFCCC to fulfil Australia's reporting obligations under the UNFCCC. The emission estimates contained in this Report for 1990–2020 will be internationally reviewed and finalised in accordance with UNFCCC and Kyoto Protocol processes.

The Report has been prepared in accordance with the *Revision of the UNFCCC reporting guidelines on annual inventories for Parties included in Annex I to the Convention* agreed by the Conference of Parties at its nineteenth session (decision 24/CP.19), and set out in document FCCC/CP/2013/10/Add.3⁵ and the supplementary reporting requirements under Article 7 of the Kyoto Protocol (decisions 6/CMP.9, 2/CMP.8, 2 and 4/CMP.7, 15/CMP.1, and 2, 3 and 4/CMP.11).

The emissions estimates provided in this Report have been compiled in accordance with the Intergovernmental Panel on Climate Change (IPCC) *2006 IPCC Guidelines for National Greenhouse Gas Inventories* (IPCC 2006) and the *2013 Revised Supplementary Methods and Good Practice Guidance Arising from the Kyoto Protocol* (IPCC 2014). The methodologies used to estimate Australia's inventory have been improved over time and will continue to be refined as new information emerges, and as international practice evolves. In that context, the national method improvements in this Report include improvements informed by the *2019 Refinement to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories* (IPCC 2019), prepared by the IPCC and adopted at its 49th Session in May 2019. The IPCC 2019 and the *2013 Supplement to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories: Wetlands* (IPCC 2013 Wetlands Supplement) also informed the voluntary reporting of additional sources of *fugitive* emissions and certain sources in *wetlands* in this Report. The aim is to ensure that the estimates of emissions are accurate, transparent, complete, consistent through time and comparable with those produced in the inventories of other countries.

Australia's ratification of the Kyoto Protocol (KP) came into force in March 2008. This Report fulfils Australia's reporting obligations under the KP; containing net emissions for 2020 compiled using reporting rules applicable to the KP second commitment period (CP2). 2020 is the eighth and final year of the KP CP2, which entered into force on 31 December 2020. Australia implemented its CP2 commitments prior to the Doha Amendment's entry into force, consistent with Decision 1/CMP.8. The Australian Government submitted its instrument of acceptance to the Doha Amendment on 9 November 2016.

5 <http://unfccc.int/resource/docs/2013/cop19/eng/10a03.pdf#page=2>

1.1.2 Gases

The Report covers sources of greenhouse gas emissions, and removals by sinks, resulting from human (anthropogenic) activities for the major greenhouse gases; carbon dioxide (CO₂), methane (CH₄), nitrous oxide (N₂O), perfluorocarbons (PFCs), hydrofluorocarbons (HFCs), sulphur hexafluoride (SF₆) and nitrogen trifluoride (NF₃). Also covered in ancillary fashion for reporting under the UNFCCC are the indirect greenhouse gases; carbon monoxide (CO), oxides of nitrogen (NO_x), and non-methane volatile organic compounds (NMVOCs). Sulphur dioxide (SO₂), an aerosol precursor, is also included because emissions of this gas influence global warming.

The Report presents emissions for each of the major greenhouse gases as carbon dioxide equivalents (CO₂-e) using the 100-year global warming potentials (GWPs) contained in the 2007 *IPCC Fourth Assessment Report* (IPCC 2007)⁶. As greenhouse gases vary in their radiative activity, and in their atmospheric residence time, converting emissions into CO₂-e allows the integrated effect of emissions of the various gases to be compared.

1.1.3 Sectors

Emissions and removals have been grouped under five sectors that have been defined by the IPCC.

These represent the main human activities that contribute to the release or capture of greenhouse gases into, or from, the atmosphere:

- *Energy*
- *Industrial processes and product use*
- *Agriculture*
- *Land use, land use change and forestry (LULUCF)*
- *Waste*

For the first commitment period of the KP, Australia accounted for the *LULUCF* activities *deforestation, afforestation and reforestation* activities that had occurred since 1990 (the mandatory Article 3.3 activities). Australia expanded the land sector account in CP2. This expansion includes the mandatory Article 3.4 activity *forest management* and the voluntary Article 3.4 activities, *cropland management, grazing land management and revegetation*. Australia does not account for *wetland drainage and rewetting* in CP2, however its estimates relating to wetlands categories are reported in Chapter 6 of Volume 2 on a voluntary basis.

1.1.4 Reporting year

The Australian greenhouse gas inventory is reported for Australian financial years as key data sources, such as the National Greenhouse and Energy Reporting (NGER) system, and national energy and agricultural statistics obtained from national statistical agencies, the Australian Bureau of Agricultural and Resource Economics and Sciences (ABARES), the Department of Industry, Science, Energy and Resources (DISER), and the Australian Bureau of Statistics (ABS), are published on this basis. The year 2020 refers to the Australian financial year from 1 July 2019 to 30 June 2020, and the same format is used for other years to ensure that time series consistency is maintained. The use of financial year data is consistent with IPCC 2006 as the use of these data conforms to the normal practice of Australia's national statistical agencies and leads to more accurate emissions estimates.

6 GWPs used are, 1 for CO₂, 25 for CH₄, 298 for N₂O, 7,390 for the PFC perfluoromethane (CF₄), 12,200 for the PFC perfluoroethane (C₂F₆), 22,800 for SF₆ and 17,200 for nitrogen trifluoride (NF₃). The full list of GWPs can be found in Annex III to decision 24/CP.19 (available from the UNFCCC website in document FCCC/CP/2013/10/Add.3). GWPs are not available for the indirect greenhouse gases and in accordance with the UNFCCC reporting guidelines, are reported but are not included in the inventory total.

1.1.5 Structure of the National Inventory Report

The structure of this Report has been organised to conform to the *Revision of the UNFCCC reporting guidelines on annual inventories for Parties included in Annex I to the Convention* (FCCC/CP/2013/10/Add.3), and the supplementary reporting requirements under Article 7 of the KP (decisions 6/CMP.9, 2/CMP.8, 2 and 4/CMP.7, 15/CMP.1 and 2, 3 and 4/CMP.11).

The Report provides estimates of Australia's total net emissions in 2020, and preliminary estimates for 2021 (Annex 3), and identifies trends in emissions for each of the sectors and for the main greenhouse gases. It also provides, *inter alia*, comprehensive information on estimation methodologies and data quality; details of recalculations of emissions estimates and background on the national system and the inventory preparation processes in order to facilitate international review and comparison with the inventories of other countries.

1.1.6 Supplementary Kyoto Protocol reporting requirements

Chapters 11 to 15 of this Report (Volume 3) contain the supplementary KP reporting information on emissions and removals from the *LULUCF* Article 3.3 and Article 3.4 activities, Kyoto units, minimisation of adverse impacts in accordance with Article 3.14 and changes to the national system and registry.

1.1.7 National system

In accordance with Article 5, paragraph 1 of the KP, Australia has put in place a national system for the estimation of anthropogenic emissions by sources and removals by sinks of all greenhouse gases not controlled by the Montreal Protocol. The guidelines for national systems (annex to decision 19/CMP.1 and decision 3/CMP.11) detail the characteristics of a national inventory system (Table 1.1). This chapter describes the main components of Australia's national system.

Table 1.1 Reporting of national system characteristics against the guidelines for national systems (annex to decisions 19/CMP.1 and 3/CMP.11)

General functions

Paragraph number (decision 19/CMP.1)	Description of national inventory system characteristic	Section cross reference
10a	Establish and maintain institutional, legal and procedural arrangements	1.2
12a	Designate a single national entity	1.2
12b	Make available postal and electronic addresses of national entity	1.2
12c	Information on actors, institutional, legal and procedural arrangements	1.2
12d	Elaborate a QA/QC plan	1.2
12e	Establish process for official consideration	1.2

1 Annexes are contained in Volume 3.

1.1.8 National Greenhouse Accounts

In addition to this Report, the Department publishes a range of supporting emissions estimates that, together, constitute the *Australian National Greenhouse Accounts*. In addition to the *National Inventory Report*, the Department also prepares:

- *Quarterly Updates of Australia's National Greenhouse Gas Inventory*, which provide timely information on emissions trends on a quarterly basis;
- an overview of the *State and Territory Greenhouse Gas Inventories*; and
- the *National Inventory by Economic Sector*, comprising emissions estimates by economic sector (rather than by IPCC sectors, as in this Report).

These reports provide additional information with respect to Australia's emissions on both a regional and industry basis and are available on the Department's website: <https://www.industry.gov.au/policies-and-initiatives/australias-climate-change-strategies/tracking-and-reporting-greenhouse-gas-emissions>

1.2 National inventory arrangements

1.2.1 Institutional, legal and procedural arrangements

Single national entity

In accordance with the guidelines for national systems (decision 19/CMP.1 annex paragraph 12(a) and decision 3/CMP.11), the responsibility for Australia's national inventory was assigned to a single agency, the Department of Industry, Science, Energy and Resources (the Department) in the year 2020.

The Department has responsibility for all aspects of activity data co-ordination, emissions estimation, quality control, improvement planning, preparation of reports, and submission of reports to the UNFCCC on behalf of the Australian Government.

The designated representative with overall responsibility for the national inventory is:

General Manager
National Inventory Systems and International Reporting Branch
Department of Industry, Science, Energy and Resources
Australian Government
GPO Box 2013
Canberra ACT 2601
AUSTRALIA

nationalgreenhouseaccounts@industry.gov.au

Capacity for timely performance of the general and specific functions of the national system

The guidelines for national systems (decision 19/CMP.1 annex paragraph 10(b) and decision 3/CMP.11) require that there is sufficient capacity for the timely performance of national inventory system functions. The production of high quality and timely greenhouse gas inventories is a resource-intensive process. To meet these objectives of quality and timeliness Australia has invested significant financial and human resources through the development of capital assets, training of Department staff and the contracting of expert consultants as needed.

IT software systems

Estimation of emissions is conducted by the Department, using the Australian Greenhouse Emissions Information System (AGEIS) and, for the *LULUCF* sector, the Full Carbon Accounting Model (FullCAM) (see Figures 1.1 and 1.2).

The AGEIS has been designed to meet the requirements for national inventory systems and is an integral part of the inventory preparation and publishing processes. In particular, it fully integrates quality control procedures into the compilation process as well as centralising emissions estimation, inventory compilation and reporting, and data storage activities. The AGEIS provides high transparency levels for the inventory, with emissions data for the set of *National Greenhouse Accounts* publicly accessible through an interactive web interface:

<https://ageis.climatechange.gov.au/>.

The AGEIS is continuing to be expanded and refined to support the range of *National Greenhouse Accounts* in accordance with the *AGEIS Strategic Plan*. Recent investment includes development to support emission estimation in accordance with Paris Agreement requirements, progressive integration of models to estimate Australia's emissions projections, and work to integrate quarterly emission estimation models into AGEIS.

While the AGEIS is used for final preparation of the *National Greenhouse Accounts*, the inventory uses FullCAM to estimate emissions and removals from the *LULUCF* sector and *KP-LULUCF* activities. FullCAM continues to be developed to improve its fully spatially explicit, process-based ecosystems modelling capability by applying techniques described in the *2013 Revised Supplementary Methods and Good Practice Guidance for LULUCF Arising from the Kyoto Protocol* (IPCC 2014) as well as significantly updated national datasets. To date, the modelling capability has been completed for conversion of forests to other land uses (e.g. cropping and grazing), *conversion of lands to forest*, *croplands remaining croplands*, *cropland management*, the grassland component of *grasslands remaining grasslands* and *grazing land management* and the fire component of *forests remaining forests*.

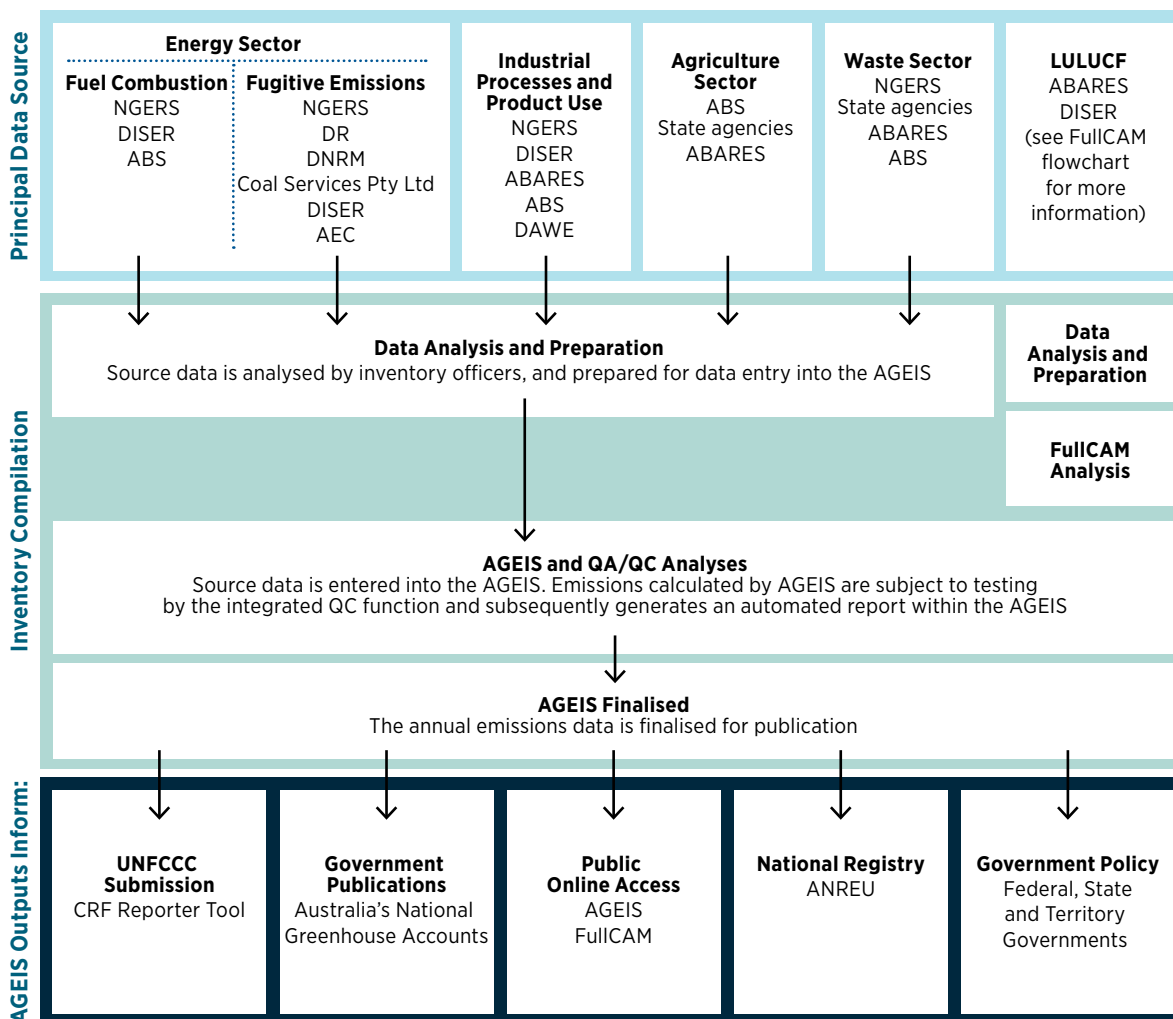

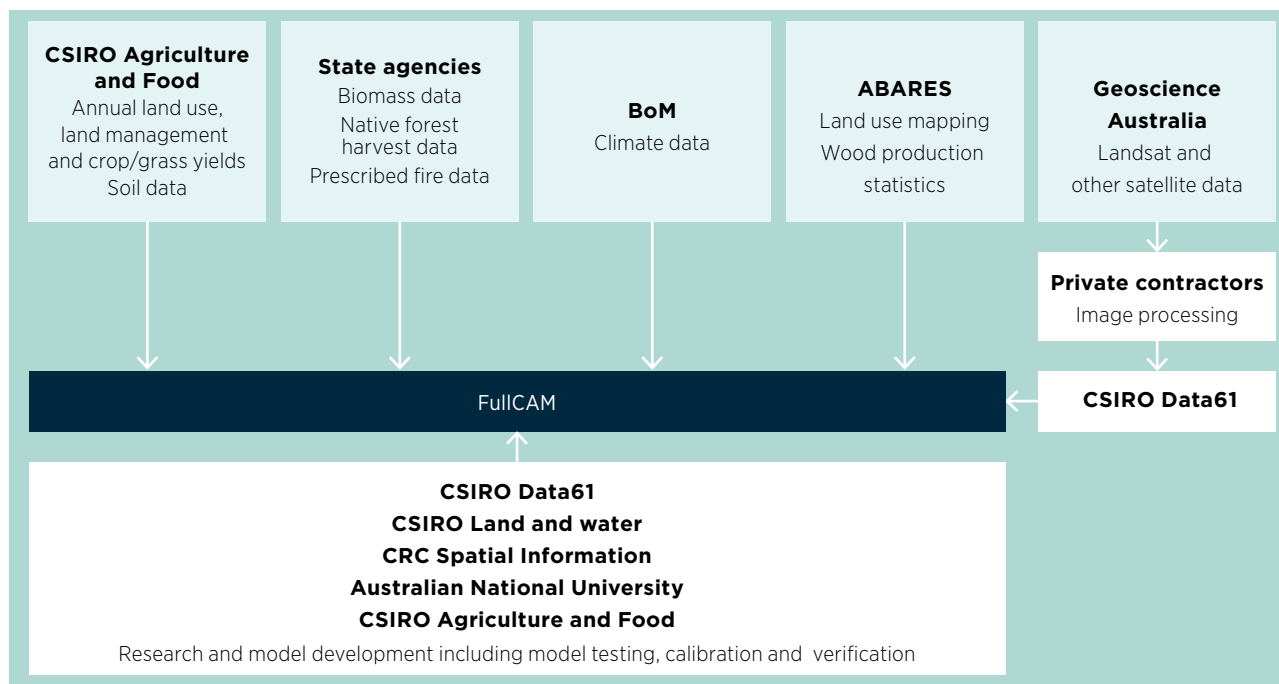

Figure 1.2 FullCAM institutional arrangements

Technical competence of staff

Department of Industry, Science, Energy and Resources staff and external consultants have extensive experience in inventory preparation. The Department aims to maximise the number of staff who have undergone the UNFCCC reviewer training and participated in UNFCCC Expert Review processes. All senior technical staff are qualified reviewers and have been accepted onto the UNFCCC Roster of Experts. Where particular technical expertise is not available within the Department, expert consultants are engaged to undertake analysis and review work.

Process for official consideration and approval of the Inventory

The draft method improvements and estimates are considered by the National Greenhouse Gas Inventory Committee, which comprises representatives of the Australian, state and territory governments. Key domestic users of national inventory data are also engaged in the formal review arrangements through the National Inventory Users Reference Group. This group includes Australia’s premier science organisation, academics, sectoral experts from the consulting sector and industry representatives. The National Inventory User Reference Group meets once or twice a year.

The National Greenhouse Gas Inventory Committee and the National Inventory Users Reference Group are the principal mechanisms for formal external review of the Report prior to its release.

Release of each year’s inventory and submission to the UNFCCC is approved by the Deputy Secretary of the Department.

1.2.2 Overview of inventory planning, preparation and management

Australia's inventory is prepared following a rigorous annual process which includes planning, methodology improvement, data collection and entry, the implementation of quality control and assurance measures, emissions estimation, report preparation, emissions and report review and report publication. The 17 steps of a typical annual cycle are described in detail in section 1.3.

National Greenhouse and Energy Reporting (NGER) Scheme

The NGER scheme is one of the most critical assets in the preparation of the inventory, collecting data on emissions from the *energy, industrial processes and product use* and *waste* sectors.

The legislative framework for the mandatory NGER scheme was established through the *National Greenhouse and Energy Reporting Act 2007* (Cwlth) (NGER Act). An explicit objective of the NGER Act is to collect information to support the development of the national inventory.

Under the NGER scheme, companies whose energy production, energy use, or greenhouse gas emissions (from the *energy, industrial processes and product use* and *waste* sectors) meet certain thresholds must report facility-level data to the Clean Energy Regulator (CER). The NGER scheme provides activity data inputs, such as fuel combustion, emissions factors (EF) at facility level and, in some cases, directly measured emissions.

Annual reports have been submitted by companies under the NGER scheme for Australian financial years since 2008–09. This data has been used in the preparation of this Report.

The rules for the estimation of activity data, EFs and emissions by companies are well specified and set out in the *National Greenhouse and Energy Reporting (Measurement) Determination 2008* (Cwlth) (the Determination). For further detail on the Determination see section 1.4.2.

The estimation methodologies used for company and facility emissions are estimated within the *National Greenhouse Accounts* framework ensuring consistency among the relevant accounts; national, state and territory, industry, company and facility-level inventories. Integration of the estimation methods and data is critical for ensuring that changes in emissions at the facility level are captured efficiently and accurately in the national inventory. The default methods used by companies are derived from the national inventory methods while the default EFs have been derived using the AGEIS.

The CER manages the process of input data collection from companies, data verification/auditing and the dissemination of this data to relevant agencies. The CER's Emissions and Energy Reporting System (EERS) is used for the collection of the input data from companies. Details of the NGER verification and auditing procedures are provided in section 1.2.3.

The Climate Change Authority (CCA) undertook a review of the operation of the *National Greenhouse and Energy Reporting Act 2007* and its supporting legislative instruments in 2018.

The CCA is an independent statutory agency, which provides expert advice to the Australian Government on climate change policy. The Authority is required to review the operation of the National Greenhouse and Energy Reporting legislation every five years.

In coming to its findings, the CCA consulted widely with industry, government agencies and data users and also undertook its own research and analysis.

The CCA found the NGER reporting system is working well, is generally fit for purpose and, in its current form, has strong support from industry, governments and others. More specifically it was found that the NGER scheme:

- generates a high quality dataset, which is accurate, has broad coverage and compares favourably against international schemes;
- informs government energy and emissions policies, programs and activities at both the Australian and state and territory level;
- uses approaches to measuring energy and emissions that are fit for purpose;
- helps companies better understand their energy and emissions and meet other reporting requirements;
- informs investors and others such as academics and analysts; and
- reduces duplicative reporting of emissions and energy across jurisdictions and has minimised the regulatory burden on businesses.

The *Review of the National Greenhouse and Energy Reporting legislation – final report* is publically available on the Climate Change Authority's website at: <https://www.climatechangeauthority.gov.au/publications/review-national-greenhouse-and-energy-reporting-legislation-final-report>.

The Australian Government's response to the review is available at <https://www.awe.gov.au/about/reporting/obligations/government-responses/cca-review-nger>.

Details on other data sources used in the preparation of the inventory are contained in sections 1.2.3, 1.3.2 and 1.7.

1.2.3 Information on the quality assurance/quality control plan

This section outlines the major elements of the quality assurance/quality control (QA/QC) plan. Australia's QA/QC plan is documented in full in the *National Inventory Systems: Quality Assurance/Quality Control Plan* (QA/QC plan).

The IPCC defines QC as a system of routine technical activities to measure and control the quality of the inventory as it is being developed. A basic QC system should provide routine and consistent checks to ensure data integrity, correctness, and completeness, identify and address errors and omissions, and document and archive inventory material and record all QC activities.

QA is a planned system of review procedures conducted by personnel not directly involved in the inventory compilation and development process.

The QA/QC processes deployed by the Department aim to conform to the IPCC Guidelines and Supplementary Methodologies (IPCC 2006, 2014). These processes further aim to contribute to the production of inventories which are accurate, in which uncertainties are reduced to the extent practicable, and in which the estimates are transparent, documented, consistent over time, complete, and comparable. The QA/QC plan identifies key risks to the achievement of these objectives and sets out the mitigation strategies employed to ensure that the quality objectives for emissions estimates are attained.

Key risks to the attainment of the defined quality objectives are identified at each level of inventory preparation, including the measurement of data at the facility level, the collation of activity and other input data by the Department and other agencies, and the process of emissions estimation.

Principal mitigation strategies are discussed below. A detailed summary of the quality control measures employed in the preparation of Australia's inventory is presented in Annex 6 (Volume 3 of this Report).

Systems have been established to monitor the outcomes of the mitigation strategies and control measures, principally managed through the AGEIS (see below). Each year, an evaluation of the data collected under the

monitoring systems is undertaken and documented in the *National Inventory Systems: Evaluation of Outcomes* document. Following consideration of the *Evaluation of Outcomes* document, improvements to the inventory are then effected through the *National Inventory Systems: Inventory Improvement Plan*.

NGER scheme data – quality control procedures

The principal data source for this inventory is the NGER scheme. The quality control system for this data is critical for the quality for the inventory as a whole.

Use of Standards

A key mitigation strategy to manage risks associated with measurement error is to ensure that rules for emissions estimation are well specified. Rules for the estimation of emissions by companies have been developed to conform to the *National Greenhouse Accounts* framework and aims to ensure that consistent estimation methods are deployed at the national, state and territory, industry, company and facility level. This consistency is critical to ensure policy efficiency, and to engender confidence in the company estimates by ensuring the methods used are also consistent with IPCC 2006.

The Determination is supplemented by the referencing of standards for sampling and analysis of key data inputs. For example, for the estimation of facility-specific EFs, NGER methods reference relevant Australian, ISO, and equivalent international standards (EU, US) for sampling and analysis of relevant fuel qualities and characteristics (such as carbon content). These standards provide, *inter alia*, sample handling protocols and tolerance levels for precision (repeatability and reproducibility), as well as for the management of bias.

Where possible, the NGER scheme has been designed to use the data systems that operate to support other regulatory functions such as commercial or taxation activities. In particular, measurement of commercial activity data in Australia is regulated by the *National Measurement Act 1960* and *National Measurement Regulations 1999* and, for utilities, by state government regulations. These legislative instruments underpin the quality of all activity data subject to commercial operation that are used in the *National Greenhouse Accounts*. For example, the *National Measurement Regulations 1999* specify maximum tolerances for measurement error for any amount of solid fuel subject to commercial activity.

Certain data sources are also governed by the regulations of the taxation system. For example, data on liquid fuels are governed by the requirements of the *Excise Tax Act 1901* which places strict tolerance limits on measurement error. To an important extent, the quality of commercial and taxation data in Australia underpins the quality of emissions data reported under the NGER scheme.

Validation of NGER data

In order to facilitate accurate reporting of information, the CER provides education and technical support to assist reporting entities to understand and implement their obligations under the NGER scheme. The CER monitors compliance with the NGER scheme through systematic analysis of reported data for qualitative or quantitative errors and through consideration of findings from its annual audit program. Where reporting errors are identified and confirmed, the CER may require that the data is corrected through resubmission.

Independent auditing of NGER data

The NGER Act provides for a risk-based program for the independent verification of NGER data. Under the NGER Act, the CER has the authority to commission, or to require a reporting entity to commission, an external audit on aspects of the entity's compliance with the NGER Act and associated legislative instruments. Sections 73 and

74 of the NGER Act define the circumstances under which a greenhouse and energy audit may be initiated and establishes a mechanism for Registered Greenhouse and Energy Auditors to undertake audit engagements.

The requirements for the preparation, conduct and reporting on greenhouse and energy audits are set out in the *National Greenhouse and Energy Reporting (Audit) Determination 2009* (Cwlth). Greenhouse and energy audits may only be conducted by a greenhouse and energy auditor who has been registered under section 75A of the NGER Act. The purpose of greenhouse and energy audits is to determine the extent to which entities that are required to register and report under the NGER Act have, or have not, complied with its requirements.

The NGER Act empowers the CER to direct a reporter to initiate a greenhouse and energy audit, where:

- there are reasonable grounds to suspect that an entity that is required to register and report under the NGER Act has contravened, is contravening, or is proposing to contravene either the NGER Act or associated legislative instruments; or
- it is determined that, for another reason, an audit of an entity's compliance with one or more aspects of the NGER Act or the associated legislative instruments is necessary.

Audits may examine:

- the reporting of emission sources, energy consumption and energy production; and
- the effectiveness of internal controls associated with data collection, record keeping and reporting processes. Significant penalties may apply to an entity's Executive Officers for contravention of the NGER Act.

In addition, many companies voluntarily engage external auditors to review their reports prior to submission to the CER.

The CER has adapted quickly to the COVID-19 pandemic, providing guidance and support to auditors and regulated entities, through alternative assurance mechanisms, where feasible. As a result, its audit program was not materially impacted.

Time series consistency with audited data

For the preparation of the national inventory, data collected under the NGER scheme has been checked for time series consistency with facility data available for previous years either from the NGER scheme or, in some cases, data collected previously for the inventory, e.g. fuel combustion in the electricity generation sector or other facility reporting programs.

Confidential data

Where reporting at a disaggregated level could lead to the disclosure of confidential information emissions data is treated as confidential and aggregated with other sectors before publication. Confidential data utilised in the national inventory is currently collected from companies under NGER. This data is subject to the *validation, independent auditing and use of standards* controls outlined above.

Processes have been put in place to ensure QA/QC is recorded in the Report for confidential emissions sectors. For sectors where emissions data is confidential the implied emissions factors (IEF) have been published for the relevant sub sectors (see sections 4.3.9, 4.4.10 and 4.5.7). As a quality control, the IEF for Australia are plotted and compared against a distribution of implied emissions factors for all other Annex I Parties.

In order to maintain continuity in the compilation of *industrial processes and product use* emissions estimates, the Department engaged the external consultant previously used to collect activity data and EF information to undertake a quality control assessment of the full time series of activity data including confidential data from

before the introduction of the NGER scheme. This work is of particular importance in industrial processes where confidentiality of historical activity data poses some challenges for the assessment of time series consistency.

Other datasets – quality control procedures

Where the inventory uses official national statistics, the quality control of this data is managed by the source agencies. The ABS publishes assessments of data quality and quantitative estimates of sampling errors for transport and agriculture activity data. National level energy activity data are produced by the Department through its annual *Australian Energy Statistics* (AES, DISER 2020). The AES data was reviewed and 'benchmarked' by the ABS in its role of national statistics co-ordinator.

With respect to electricity, explicit reconciliations of energy data are undertaken by comparing data collected under NGER contained in the AES and the estimates produced by the Australian Energy Council (AEC) and the Australian Energy Market Operator (AEMO), which are all undertaken for slightly differing reasons and with slight differences in coverage.

Explicit reconciliations of data are also undertaken with respect to emissions estimates on forest conversion. Geospatial data on forest conversion is compared to independent datasets produced by other agencies, for example the Queensland Department of Environment and Science and the New South Wales Department of Planning, Industry and Environment. Information provided by other state agencies in relation to permits issued for land clearing have also been used in assessing the land cover change data obtained from Landsat.

Tier 1 quality control checks – emissions estimation

Emissions estimation is conducted through the use of the AGEIS software (apart from the *LULUCF* sector). Management of the AGEIS is conducted in accordance with the Control Objectives for Information and related Technology (COBIT) framework. The AGEIS is subject to performance audit by the Australian National Audit Office.

For this inventory and associated time series, there are around 4.8 million data inputs in the *non-LULUCF* sectors. To facilitate the management of such a large amount of data, AGEIS was specifically developed to play a central role in the quality control of the national inventory. Key tier 1 QC controls have been systematically built into the operation of the AGEIS. Auditable checks are undertaken *inter alia* to reduce the risks of errors associated with the input of activity data, missing data, recalculations and the time series consistency of generated emissions estimates.

Input data and IEFs are also checked for recalculations and time series consistency prior to submission using AGEIS and the CRF reporter tool. The allocation of roles and responsibilities of staff provide for the separation of data handling and data approval roles within the Department to improve accountability.

Extensive internal verification of emissions estimates, as well as external acceptance testing of system integrity and functionality, is undertaken during the development of the AGEIS. Emissions estimated by the AGEIS are compared with those previously reported using traditional spreadsheets to ensure emissions are calculated correctly, that parameter and emissions units are correctly recorded, and that data is correctly aggregated from lower to higher reporting levels. Implementation of new estimation methodologies are undertaken using a dual estimation approach, which ensures that AGEIS emissions estimates are verified independently.

Australia's QA/QC Plan is designed to align with the requirements of the IPCC 2006. The set of tier 1 QC procedures for the inventory compilation process specified in the IPCC 2006 along with the relevant control measure reference in Australia's QA/QC Plan, are identified in Table 1.2.

Table 1.2 Implementation of tier 1 quality control checks

Tier 1 QC activity: Checks^(a)	Control Measure^(b)	Implementation / Comment
Assumptions and criteria for the selection of activity data and EFs documented	3.E.1	Documented in the National Inventory Report.
Transcription errors in data input and reference	2.A.1-3, 2.B.2.	Errors checked for using internal AGEIS data verification checks. AGEIS fully integrated with the UNFCCC CRF Reporter Tool removing risk of errors in CRF tables. Error checks are also implemented during the pre-processing of input data. Bibliographical data references checked for correct citation.
	2.A.4	FullCAM inputs database is checked for transcription errors between source documents and database.
Emissions are calculated correctly	3.A, 3.B, 3.C	Extensive testing during AGEIS development phase and when new methods introduced. Selected dual estimation process using traditional spreadsheets.
Parameter and emissions units are correctly recorded and that appropriate conversion factors are used	3.A, 3.B, 3.C	Extensive testing during AGEIS development phase and when new methods introduced. Selected dual estimation process using traditional spreadsheets. Extensive testing during development of FullCAM functionality. Ongoing testing undertaken on an operational basis.
Integrity of database files	3.A1-3	Extensive verification/external acceptance testing during the AGEIS development phase. Automated testing of FullCAM database files. Selected dual estimation process using traditional spreadsheets. Database system and operation documentation updated and archived.
	2.A.5	Integrity of FullCAM inputs database files checked.
Consistency in data between source categories	3.A.1-3	Parameters (activity data, constants, EFs) which are common to multiple sources are entered into global or general data tables so data is only entered once into database.
	2.E.1	FullCAM provides a common platform using a common inputs database for <i>LULUCF</i> estimates. The FullCAM inputs database is reviewed to ensure that parameters that are common between source categories are not differentiated.
Movement of inventory data among processing steps is correct	3.A.1-3	Extensive testing during AGEIS development phase and when new methods introduced. Standard reconciliation reports are run to ensure correct aggregation of emissions estimates. Cross checking data between FullCAM, AGEIS and the CRF for consistency.
Uncertainties in emissions and removals are estimated or calculated correctly		Independent review by CSIRO completed.
Time series consistency/ Methodological and data changes resulting in recalculations	3.C, 3.D	Where changes are made to methods or activity data the full time series of emissions is recalculated, the AGEIS and FullCAM ensure consistent use of methods across time series.
Completeness	B.1-2, B.1-4	Checked through CRF Reporter Tool. Mass balance checks undertaken for fuel, carbonates, biomass and synthetic gases. FullCAM has a mass balance check incorporated at each stage of the model process.
Trend	3.D.1-2	Activity data, emissions and IEFs are compared with the previous year's estimates, and across entire time series, through the AGEIS and CRF Reporter Tool.
Review of internal documentation	3.E.1-3	All activity data, emissions factors and algorithms are archived within AGEIS. Past inventories may be reproduced using AGEIS. Electronic and hard copies of each year's NIR and methodology are kept in a safe. All bibliographical data references are archived within the AGEIS and in a hardcopy library. FullCAM software, simulations and activity data are stored on a secure server and include a documented backup service with offsite storage.

Table 1.3 Results of reconciliation quality control objectives

Test	Objective (per cent difference)	Result
CM 2.A.1 Accuracy/Completeness: Reconciliation of data submitted into AGEIS and reference data: electricity emissions and coal mine fugitive emissions.	< 2	Achieved
CM 2.B.2 (i) Completeness: Reconciliation of data submitted into AGEIS and reference data: fossil fuels consumption	<0.1	Achieved
CM 2.B.2 (ii) Completeness: Reconciliation of data submitted into AGEIS and reference data: carbonates consumption	<1	Achieved
CM 2.B.2 (iii) Completeness: Reconciliation of data submitted into AGEIS and reference data: biomass consumption	<1	Achieved
CM 2.B.2 (iv) Completeness: Reconciliation of data submitted into AGEIS and reference data: wastewater consumption	<1	Achieved
CM 2.B.2 (vi) Completeness: Reconciliation of data submitted into AGEIS and reference data: synthetic gas consumption	<0.1	Achieved
CM 3.B.1 (i) Carbon balance: Reconciliation of data submitted into the AGEIS and national inventory: fossil fuel consumption	<0.01	Achieved
CM 3.B.1 (ii) Carbon balance: Reconciliation of data submitted into the AGEIS and national inventory: carbonates consumption	<0.01	Achieved
CM 3.B.1 (iii) Carbon balance: Reconciliation of data submitted into the AGEIS and national inventory: biomass consumption	<0.001	Achieved
CM 3.B.1 (iv) Carbon balance: Reconciliation of data submitted into the AGEIS and national inventory: wastewater consumption	<0.001	Achieved
CM 3.B.1 (vi) Carbon balance: Reconciliation of data submitted into AGEIS and reference data: synthetic greenhouse gases	<0.001	Achieved
CM 3.B.1 (viii) Carbon balance: Reconciliation of carbon in fossil fuels, carbonates, synthetic gases, wastewater data submitted into AGEIS and carbon contained in emissions or stored in products or destroyed.	< 0.01	Achieved
CM 3.B.2 (i) Reconciliation between national inventory and sum of State and Territory inventories	<0.1	Achieved
CM 3.B.2 (ii) Reconciliation between national inventory and national inventory by economic sector	<0.1	Achieved
CM 3.B.2 (iii) Reconciliation between national inventory and output from the AGEIS	<0.1	Achieved

Tier 2 quality control checks

Category-specific QC (tier 2) checks are conducted for all sectors to test for completeness, international comparability and verification of country-specific parameters.

Completeness and accuracy are tested through the operation of mass balance checks. The application of mass balance constraints for carbon in fuels, carbonates, biomass wastes, and hydrofluorocarbons and nitrogen balances for domestic and industrial wastewater constitute tier 2 quality control measures. All carbon entering the economy in fuels is accounted for, either as emissions from fuel combustion, emissions from the use of fossil fuels as reductants, non-energy uses, use of biomass sources of energy, or international bunkers. Carbon balances for biomass, carbonates and synthetic gas consumption have also been implemented. The results of these checks against the principal quality objectives are set out in Table 1.3. Detailed results of the application of these balances are reported in Annex 6 of Volume 3.

International comparability of emissions estimates is systematically tested through comparisons of the IEFs obtained for significant sources of the Australian inventory with the distribution of IEFs for all other Annex I Parties. The results of these analyses are included in the QA/QC discussions of individual sector sources in this Report.

For the *energy, industrial processes and product use* and *waste* sectors, systematic verification tests are undertaken for country-specific parameters, such as EFs utilising data collected under the NGER scheme. The tests are undertaken in accordance with the decision tree (Figure 1.3). Country-specific parameters are tested against NGER datasets that meet the prescribed conditions. If the mean of the NGER dataset is significantly different to the country-specific parameter, the parameter may be revised to reflect the new information. The results of the test are presented in the *National Inventory Systems: Evaluation of Outcomes* document.

The empirical research program set out in the *National Inventory Improvement Plan* is designed to generate information to provide the basis for verification tests for parameters in either tier 2 or tier 3 methods where private measurement activity is not undertaken (see section 10.5 of Volume 2 for more details).

In addition, country-specific parameters may also be subjected to verification tests on an ad hoc basis as new information is obtained.

Integrated Quality Control: AGEIS

AGEIS incorporates functionalities to achieve efficiencies in the QC process, mitigate the risk of transcription errors during QC activity checks, and centralise all QC activities for review and archiving.

AGEIS can conduct tier 1 and tier 2 quality controls based on user-defined selections of QC activities. It can also populate the *National Inventory Systems: Evaluation of Outcomes* report to record the results of the monitoring program designed to implement the risk mitigation strategies and quality control measures detailed in the QA/QC Plan.

Australia's QA systems operate at a number of levels. QA controls that are implemented annually include:

- the review of the Report, prior to submission to the UNFCCC, by the National Greenhouse Gas Inventory Committee, which comprises representatives of state and territory governments. This is the principal formal external review mechanism for the report before it is finalised;
- the prioritisation and review of inventory improvements by the National Inventory Users Reference Group;
- review by external consultants for specified sectors;
- QA of remote sensing imagery and data inputs for the *LULUCF* (Chapter 6 Appendix A, Volume 2);
- the inventory is potentially subject to audit by the Australian National Audit Office (ANAO). The ANAO is an independent office established under the *Auditor-General Act 1997*. It conducts performance audits of government agencies operating under the Standard on Assurance Engagements ASAE 3500 Performance Engagements issued by the Australian Auditing and Assurance Standards Board (AUASB). ANAO reports are tabled in the Australian parliament and subject to review by the Joint Committee of Public Accounts and Audit (JCPAA). The ANAO undertook a performance audit of the national inventory in 2009–10 and 2016–17. Further information on the most recent audit is provided below;
- opening the inventory emissions estimates and methods for public review through the release of transparent and easily accessible information via the Department and the AGEIS webpage. Industry and public feedback is accepted through the inventory e-mail facility nationalgreenhouseaccounts@industry.gov.au; and
- UNFCCC expert review team processes which aim to review and improve the quality of all Annex I Parties' inventories in an open and facilitative manner. Australia's inventory has been reviewed by in-country teams in 2002, 2005, 2008, 2010 and 2015, by a desk review in 2017, with centralised reviews in other years. Annex 6 (Volume 3) shows outstanding recommendations from the review report on the submission in 2020 have been implemented, or will be addressed in the future.

Inverse modelling of emissions

Inverse modelling has been deployed in Australia to better understand the characterisation of point and dispersed emissions sources with the aim of improving the national inventory methods over time.

In 2019, the CSIRO undertook analysis of methane plumes in the Surat Basin – a region in Queensland rich in economic activity that is also methane intensive including coal seam gas extraction, coal mining, beef and feedlot production, abattoirs, sewage and water management activities.

The CSIRO operated two flux towers at either end of the Basin and obtained continuous measurements over 2016 to obtain a ‘top-down’ estimate of methane emissions in the Basin for the year (Luhar et al 2020).

A regional inventory for the Basin using national inventory methods was also constructed to provide a test and quality assurance for national inventory methods. The estimate for methane emissions for the Surat Basin for 2016 for this regional inventory was within 10 per cent of the CSIRO’s independent, top-down analysis (DISER, 2021).

For the CSG zone within the Surat Basin, where CSG operations are concentrated and account for around 60 per cent of all emissions, there was also good agreement between the top-down estimates of Luhar et al 2020 and the bottom-up inventory using national inventory methods for methane reported in DISER 2021, with the estimates based on inventory methods being 18 per cent higher.

The good fit between the regional inventory using national inventory methods and the CSIRO ‘top-down’ data provides strong assurance of the quality of national inventory methods for methane.

The close fit is partly the result of recent improvements to estimation methods introduced into the national inventory since 2016. These include updated methods for fugitive emissions from CSG production, methane emissions from combustion slip at CSG operations, manure management, water bodies and abandoned coal seam gas wells which are estimated to have raised the estimate of methane emissions in the Surat Basin by around 24 per cent in 2016.

More ‘top-down’ empirical work is underway in Australia and all methods will be kept under review as new empirical studies on methane fluxes emerge.

Monitoring of atmospheric hydrofluorocarbon (HFC) concentrations has been undertaken by the CSIRO at the Cape Grim Baseline Air Pollution Station in Tasmania since the mid 1990s.

Each year, the Department commissions CSIRO to make an independent, ‘top-down’⁷ estimate of annual emissions of HFCs from Australia and then compares this information with estimates of HFC emissions using the national inventory ‘bottom-up’ methods as part of its routine quality assurance program. The CSIRO analysis is also used to inform the gas speciation of Australia’s HFC inventory.

The CSIRO analysis (2021) is especially valuable because:

1. All emissions of HFCs are anthropogenic, and must be counted within the national inventory (unlike methane, for example, where some sources are considered to be non-anthropogenic), which simplifies the comparison estimates generated by ‘top-down’ and ‘bottom-up’ approaches; and
2. The national inventory ‘bottom-up’ methods are recognised to produce estimates with considerable uncertainties (given the absence of direct observations of leakages of HFCs from equipment, like air-conditioning, in many millions of pieces of equipment across the country).

⁷ ‘Top-down’ estimates are derived from measurements of HFC concentrations in the atmosphere to deduce an estimate of emissions from all sources for a region. ‘Bottom up’ estimates are derived from equations that relate emissions to observed activity data for specific point-sources – such as the number of air-conditioners in the economy.

In the inventory, the long run losses of HFCs are able to be determined with high confidence, since all imports of HFC gases are subject to mandatory licensing under the *Ozone Protection and Synthetic Gas Management Act 1989*, and because all of these gases, used in equipment such as air-conditioning or refrigeration, will eventually leak out into the atmosphere unless they are captured and destroyed through a single facility managed by Refrigerant Reclaim Australia.

The time profile of these HFC losses is less well-known, however, depending on factors including rates of leakage from a wide variety of equipment and the rate of recycling of gas at the point of equipment disposal in the economy.

Comparison of the CSIRO and NIR estimates of HFC emissions is contained in section 4.8.

Specific reviews of sectoral methodologies that have been performed by expert consultants that are not involved in the inventory preparation process are described in Table 1.4.

Table 1.4 Expert reviews of methodologies and activity data

Year of Review	Categories reviewed
2002-2003	4A Enteric Fermentation and 4B Manure Management. (CSIRO, ASIT Consulting, QDNRME, Hassell and Associates Pty. Ltd) Estimating Greenhouse Gas Emissions from Residential Firewood Use (J. Todd)
2004	Review of Savanna burning (CSIRO expert M. Meyer)
2005-06	Emissions factors for liquid fuels (GHD Pty Ltd) Estimating Greenhouse Gas Emissions from Residential Firewood Use (J.Todd)
2006	Methodologies in the iron and steel and petroleum refining sectors (GHD Pty Ltd) Industrial wastewater and waste incineration methodologies (O'Brien Consulting) Flooded decommissioned coal mines (L. Lunarzewski, Consultant)
2007	Review of Industrial processes and product use sector (M. Tsaranu, international expert from UNFCCC reviewer roster) Review of Waste sector (Hyder Consulting 2007a,b)
2008	Review of key FullCAM model parameters and assumptions in the LULUCF sector (M. Apps, W. Kurts, P. Smith and Q. Zhang, international experts from UNFCCC review roster and/or authors of IPCC Guidelines)
2009	Review of waste generation and disposal improvements; and Review of DOCf values (S. Guendehou, international expert from UNFCCC reviewer roster)
2010	Australian National Audit Office (ANAO) audit of the national greenhouse gas inventory program
2011	4E. Review of Prescribed Burning of Savannas (CSIRO Marine and Atmospheric Research) Review of the characteristics of liquid fuels used in the National inventory (Orbital Australia 2011a)
2011	Review of confidential data handling practices, C. O'Keefe, CSIRO 2011 Estimating Greenhouse Gas Emissions from Residential Firewood Use (J.Todd)
2015	Review of Agriculture, Cropland and Grassland methods, FullCAM and Agriculture Advisory Panel
2015	Review of Forest Management, (S. Federici international expert from UNFCCC reviewer roster)
2016	Review of deforestation and treatment of natural disturbances under UNFCCC accounting (S. Federici international expert from UNFCCC reviewer roster)
2017	Review and update of key parameters used by FullCAM in modelling carbon fluxes in forests (by CSIRO experts K. Paul and S. Roxburgh)
2017	ANAO audit of the national greenhouse gas inventory program
2018	Climate Change Authority review of the operation of the <i>National Greenhouse and Energy Reporting Act 2007</i> and its supporting legislative instruments
2021	Review of wastewater emissions from abattoirs and other meat processing facilities (5.D.2) and associated update to COD concentrations, as well as the inclusion of emissions from seafood processing (Point Advisory, 2021).

Australian National Audit Office (ANAO) Performance Audit: 2016-17

The ANAO is an independent office established under the *Auditor-General Act 1997*. Its purpose is to drive accountability and transparency in the Australian Government sector through quality evidence based audit services and independent reporting to Parliament, the Executive and the public, with the result of improving public sector performance.

The ANAO conducts performance audits of government agencies operating under the Standard on Assurance Engagements ASAE 3500 Performance Engagements issued by the Australian Auditing and Assurance Standards Board (AUASB). ANAO reports are tabled in the Australian Parliament and subject to review by the Joint Committee of Public Accounts and Audit (JCPAA).

The ANAO undertook a performance audit of the national inventory over nine months (August 2016 to April 2017). Its objective was to assess the effectiveness of arrangements for the preparation and reporting of Australia's greenhouse gas emissions estimates in the *National Inventory Report 2014 (revised)* for the year 2014.

Through the course of the audit the ANAO:

- examined Department records relating to the preparation of the estimates, including UNFCCC and departmental guides, implementation plans, quality assurance/quality control documents, and general governance documentation,
- examined ten inventory sectors representing more than 50 per cent of national emissions; comprising over 5250 data points across more than 158 data types contained in spreadsheets supporting the entry of data into AGEIS,
- examined key IT controls supporting AGEIS and FullCAM, and
- interviewed Department staff and sought input from the public and key stakeholders.

The ANAO reported that,

- the Department has established appropriate processes to prepare, calculate and publish Australia's national inventory for the year 2014,
- emissions estimates have been calculated using relevant contemporary data,
- appropriate quality assurance and control procedures are in place for inventory data processing, emissions calculations and reporting, and
- the aggregate impact of data issues identified in the national inventory across the time series 1990-2014 was calculated by the Department as less than 0.1 per cent per year.

All data issues identified by the ANAO have been addressed or corrected. The ANAO also made a number of recommendations relating to improving the data accuracy, security and governance arrangements for the preparation, calculation and publication of the national inventory. Measures to address aspects of these recommendations were implemented through the course of the preparation of the *National Inventory Report 2015*.

One such measure was a "Rounding policy for AGEIS inputs" to promote consistent decision making in inventory compilation. The policy specifies the number of decimal places to be employed for inventory input parameters, molecular factors and activity data used to generate emissions estimates via AGEIS. It has also been incorporated into the *National Inventory Systems: Quality Assurance/Quality Control Plan (QA/QC plan)*. Measures to address outstanding aspects have been included in the *National Inventory Improvement Plan*.

Climate Change Authority review of the operation of the National Greenhouse and Energy Reporting Act 2007 and its supporting legislative instruments

The Climate Change Authority (CCA) undertook a review of the operation of the *National Greenhouse and Energy Reporting Act 2007* and its supporting legislative instruments in 2018.

The CCA is an independent statutory agency, which provides expert advice to the Australian Government on climate change policy. The Authority is required to review the operation of the National Greenhouse and Energy Reporting legislation every five years.

In coming to its findings, the CCA consulted widely with industry, government agencies and data users and also undertook its own research and analysis.

The CCA found the NGER reporting system is working well, is generally fit for purpose and, in its current form, has strong support from industry, governments and others. The Authority found that the energy and emissions reporting scheme enjoys broad support from industry, governments and others. It is widely considered to be a best-practice approach to measuring and reporting emissions and energy and compares favourably to schemes in other countries.

The high quality data collected through the scheme is used extensively by governments and others to develop energy and climate change policies. It is also a critical input to meeting Australia's international energy and emissions reporting obligations.

The success of the scheme is underpinned by private investments in mature data collection and reporting systems by companies, and effective administration by the Regulator and the Department. The Regulator's constructive and professional approach to supporting companies to meet their obligations was singled out by many as a key driver of the success of the scheme.

The Authority identified a number of opportunities for improving the reporting scheme. Many of these can reduce costs to businesses or the scheme's administrators, while further enhancing the integrity of the data collected.

The *Review of the National Greenhouse and Energy Reporting legislation – final report* is publically available on the Climate Change Authority's website at <https://www.climatechangeauthority.gov.au/publications/review-national-greenhouse-and-energy-reporting-legislation-final-report>.

The Australian Government's response to the review is available at <https://www.environment.gov.au/about-us/accountability-reporting/taled/response-cca-review-nger>.

Verification activities

In addition to supporting the above mentioned inverse modelling of HFC emissions, the CSIRO Baseline Air Pollution Station at Cape Grim in Tasmania collects and analyses data on the concentrations of other synthetic gases – PFCs and SF₆ – with the aim of providing an independent assessment of emissions of these gases in Australia (see Chapter 4).

The Australian inventory is tested extensively for comparability with the inventories of other Annex I Parties. The IEFs and other key parameters for specified variables are reviewed for comparability against the IEFs for all other Annex I Parties. Specific t-tests are performed to test whether the IEFs derived from the Australian inventory are significantly different to the mean of all other Annex I Parties. The results of these tests are recorded in the *National Inventory Systems: Evaluation of Outcomes* document.

As the Australian inventory has transitioned to tier 3 methods for many sectors, future verification developments will focus on the development of assessments of tier 3 emissions outcomes against the results of associated tier 2 models.

1.2.4 Changes in national inventory arrangements

Changes to Australia's national inventory arrangements since the previous national inventory report are detailed in Chapter 13: Information on changes to the national system (Volume 3).

1.3 Inventory preparation and data collection, processing and storage

1.3.1 Inventory preparation

Key steps in the annual inventory preparation process (with indicative dates in parentheses) are determined by the needs of the system and output and quality objectives. The timing is determined by the UNFCCC submission timelines and data availability. Steps 1–17 below provide an overview of a typical inventory cycle. The cycle commences with a review of emissions estimation methods, allocation of tasks, selection of external consultants, and the preparation of the AGEIS for the compilation of the forthcoming inventory. The cycle is completed by external independent review provided by the UNFCCC Expert Review Teams.

Planning and methodology improvement

- (1) Preparation of the *Evaluation of Outcomes* document for the previous year (March–April).
- (2) Preparation of QA/QC and Inventory Improvement plans, taking into account Department of Industry, Science, Energy and Resources review of methodologies and activity data; UNFCCC expert review recommendations and the *Evaluation of Outcomes* document (May).
- (3) Development of investment and maintenance plan for the AGEIS, incorporating the QA/QC plan (June).
- (4) Methodology development, review, and incorporation into AGEIS (June–October).

Data collection and entry

- (5) Activity data collection, conducted annually by the Department. It is heavily reliant on NGER scheme data, and published data from Australia's economic statistics agencies, and is subject to quality control checks. (June–October)
- (6) Activity data entry into the AGEIS input database, by the Department, through predefined data entry templates (August–December).

Implementation of quality control measures

- (7) Activity data verification and quality control – the Department uses the AGEIS to systematically report a range of diagnostic statistics on the activity data to facilitate identification and correction of anomalous entries to ensure time series consistency and consistency across sectoral emissions estimates.
- (8) A designated analyst (known as a Supervisory user) investigates anomalies and records an assessment of the quality of the activity data in the system.

- (9) The data quality is checked and internally audited by a designated analyst, known as the Database Operations Manager (DOM), to provide quality control. Only when the DOM is satisfied is the input data transferred to the core database where emissions estimation are undertaken.
- (10) The AGEIS is used to generate emissions estimates for all inventory years using time series consistent methodologies.

Emissions and report review

- (11) Emissions estimates verification is undertaken by Department analysts repeating the range of tests on emissions estimates generated by the AGEIS to ensure time series consistency, consistency across sectoral emissions estimates, and accuracy of recalculations.
- (12) Completion of quality control measure tests to ensure estimates meet quality criteria.
- (13) The compiled inventory is circulated to the National Greenhouse Gas Inventory Committee of state and territory government representatives and the National Inventory Users Reference Group of inventory user representatives for comment prior to public release (February).

Report publication

- (14) Automated population of CRF tables (February–March).
- (15) Following approval by the Deputy Secretary of the Department, the inventory is available for public release.
- (16) Release of Australia's National Greenhouse Accounts and the AGEIS database of emissions estimates and background data at <https://www.industry.gov.au/policies-and-initiatives/australias-climate-change-strategies/tracking-and-reporting-greenhouse-gas-emissions> (April).
- (17) UNFCCC Expert Review of the Report and CRF tables (August–November).

Data collection, processing and storage

Data collection

Data collection to support the preparation of the *National Greenhouse Accounts* is managed centrally by the Department utilising a mix of approaches to ensure the reliable flow of data from other agencies to support inventory preparation.

The NGER scheme

As described in section 1.2.2, input data to support the preparation of the *National Greenhouse Accounts* for important elements of the *energy, industrial processes and product use* and *waste* sectors are collected using the NGER scheme.

Other data sources

Where possible, NGER scheme data sources are used for the *energy, industrial processes and product use* and *waste* sectors, supplemented by the use of other published data sources only where necessary. The collection process for other data is well-integrated with the objectives of other programmes with a strong reliance on data collected and published by Australia's principal economic statistics agencies; the ABS, and the Department's Resources and Energy Insights Branch. The Department's Resources and Energy Insights Branch have collected

energy statistics for over 40 years and use these data to meet Australia's reporting commitments to the IEA. The ABS is the national statistical agency with legislative backing for its collection powers. The ABS, in conjunction with ABARES, is the major source of agricultural activity data.

The Department employs consultants to process the satellite imagery used to determine land cover change for the *LULUCF* sector. Satellite imagery is sourced from Geoscience Australia (Australia's principal satellite ground station and data processing facility). Data to support estimates of HFCs are sourced from compulsory reporting by importers under licensing arrangements under the *Ozone Protection and Synthetic Greenhouse Gas Management Act 2003*. Solid waste disposal data are provided by the Stewardship Waste Section of the Department of Agriculture, Water and the Environment (DAWE). Disposal data are collected annually as part of the National Waste Reporting initiative.

Data processing

As described in sections 1.2.1 and 1.2.3, the estimation of emissions is conducted by the Department, utilising the AGEIS and, for the *LULUCF* sector, using FullCAM.

Data Storage

The Australian documentation systems aim to both manage and retain all data used in the estimation of emissions to provide a means for knowledge management, ensuring continuity and security of the National Inventory Systems.

The AGEIS is at the heart of Australia's documentation systems. It allows efficient electronic data management and archiving of the significant quantities of data needed to generate an emissions inventory. AGEIS data management functions include:

- archival and storage within the AGEIS database of the emissions estimates of past submissions;
- archival and storage within the AGEIS of past activity data, EF, and other parameters and models;
- archival and storage of data source descriptions, methodology descriptions, and source reference material; and
- integrated access to the documentation of data sources; methodology description and source reference material.

The aims of these systems include giving inventory staff ready access to all related materials that underpin the emissions estimates and to provide the means for replication of emissions estimates from past submissions.

The AGEIS functions are supported by some additional and important elements of the documentation system:

- documentation of the inventory's emissions estimation methodologies in the Report; and
- maintenance of a National Inventory Library of source material documents.

1.4 Brief general description of methodologies and data sources

1.4.1 Estimation methods

The Australian methodology for estimating greenhouse gas emissions and sinks uses a combination of country-specific and IPCC methodologies and EFs. These methods are consistent with IPCC 2006 and 2014, and are compatible with international practice.

In general, *Australia's National Greenhouse Accounts* utilize a mix of tier 2 and tier 3 estimation methods that incorporate:

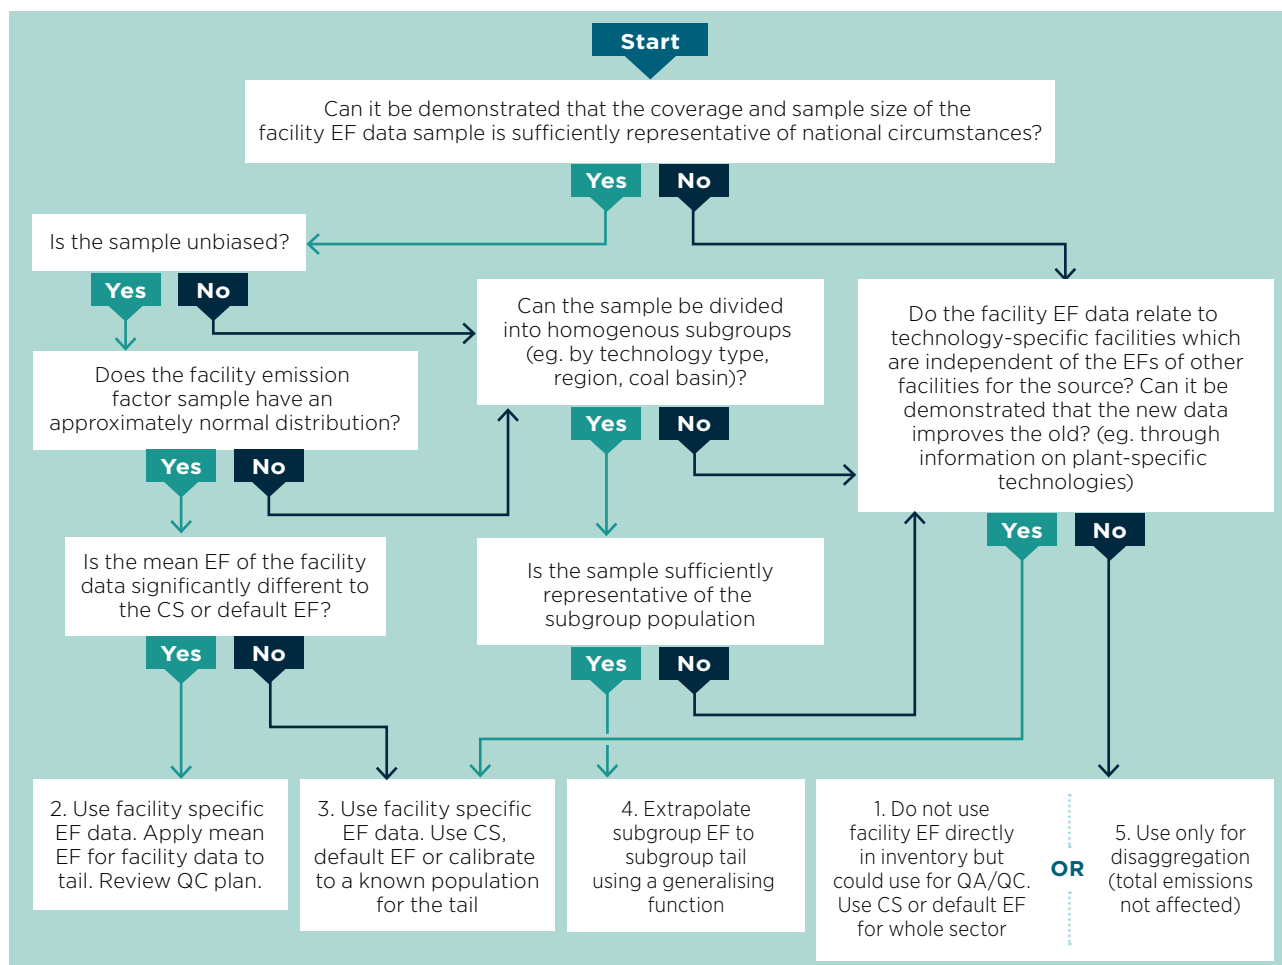

- facility-specific emissions estimation processes;
- characterisations of the capital and technology types at the point of emissions;
- dynamic relationships that link current emissions outcomes with the activity levels of previous years; and
- spatial differences in emissions processes across Australia.

The additional complexity in the methodology allows emissions to be estimated more accurately. Detailed descriptions of methods chosen are set out in the Chapters 3–7 of this Report.

Tier 3 approaches are in place for fuel combustion in the electricity industry and from fugitive emissions from underground coal mining sources. For a range of additional categories, a mix of tier 2 and tier 3 approaches will continue to be implemented over time as methods for facility-specific measurement of emissions or key data inputs are adopted by reporters under the NGER scheme and as key pre-conditions for implementation of the new methods are met. These circumstances include: the data must comply with prescribed data standards (in this case, set out in the Determination); there is a timely and comprehensive data collection system in place; and the resulting emissions estimates for the source pass the inventory quality criteria set out in the QA/QC plan (for example, in relation to completeness and international comparability).

Consistent decision making with respect to the use of facility specific EFs has been ensured through the application of a decision tree, as set out in Figure 1.3.

Figure 1.3 Consistent decision making in method selection

In particular, tier 3 methods incorporating facility-specific EF data obtained from the NGER scheme have been used where the sample size of the available NGER data is sufficiently large and when there is no evidence of bias in the distribution of the NGER EF data. For the balance of a source where there are facilities for which no facility-specific data are available, a country-specific factor is applied.

Tier 3 methods incorporating NGER facility-specific data are also able to be used in two other cases where large samples displaying characteristics of an approximately normal distribution cannot be obtained.

The first additional case relates to the situation where, within one source, a number of homogenous sub-samples can be discerned. Data for facilities with unknown characteristics can be determined by the extrapolation of information from the relatively homogenous sub sample or through calibration to a known, unbiased distribution for the population.

The second additional case relates to the situation where facility data are heavily technology dependent, and where the data for each facility are likely to be independent of one another. In particular, this is the case in the industrial wastewater category where knowledge of the technology deployed at one facility does not affect the likelihood of a certain technology being deployed at another facility where no facility data is available. In these cases, it is possible to use the facility data, where available, and it may not be appropriate to extrapolate information from the NGER sample to the remainder of a particular source. Consequently, in these cases, the original tier 2 EF has been retained for the tail of the source where NGER data has not yet been collected.

1.4.2 Data sources

The inventory is prepared using a mix of sources for activity data, including published data from national statistical agencies. The principal data sources are set out in Table 1.5.

Table 1.5 Principal data sources for the estimation of Australia’s inventory

Category (UNFCCC sector)	Principal data sources	Principal collection mechanism
Energy sector (1A1, 1A2, 1A4, 1A5)	Department of Industry, Science, Energy and Resources, NGER	Published, Mandatory data reporting system
Energy sector (1A3)	Department of Industry, Science, Energy and Resources, ABS	Published
Energy sector (1B)	NGER, Coal Services Pty Ltd, QLD DNRM, WA DMP, SA DSD, APPEA, ESAA, DIIS, NSW DIRE, Department of Industry, Science, Energy and Resources	Mandatory data reporting system, published
1.C Carbon Capture and Storage	NGER	Mandatory data reporting system
Industrial processes and product use (2)	NGER Department of Agriculture, Water and the Environment	Mandatory data reporting system Mandatory reporting of HFCs under import licensing arrangements
Agriculture (3)	ABS	Published
	ABARES	Published
Land use, land use change and forestry (4)	Geosciences Australia, ABARES, CSIRO	Memorandum of Understanding Published
	Western Australian Land Information Authority (Landgate)	Data Supply Licence Agreement Published
	Forestry Corporation of New South Wales	Data Supply Licence
	VicForests	Published
Waste (5)	Sustainable Timber Tasmania	Data Supply Licence
	NGER Department of Agriculture, Water and the Environment	Mandatory data reporting system Published

NGER (Measurement) Determination

The NGER scheme is an integral element of the national inventory system. The rules for estimation of data and emissions at the facility level by companies are set out in the Determination, which is made under subsection 10(3) of the *NGER Act*.

The structure of the Determination is designed to facilitate the integration of corporate and facility level data provided under the *NGER Act* with international data standards on greenhouse emissions.

The scope of the Determination is given by the following categories of emissions sources:

- **Fuel combustion** emissions from the combustion of fuel for energy (see Chapter 2 of the Determination);
- **Fugitive emissions** from the extraction, production, flaring, processing and distribution of fossil fuels (see Chapter 3 of the Determination);
- **Industrial processes** and product use emissions where a mineral, chemical or metal product is formed using a chemical reaction that generates greenhouse gases as a by-product (see Chapter 4 of the Determination); and
- **Waste emissions** from waste disposal – either in landfill, as management of wastewater or from waste incineration (see Chapter 5 of the Determination).

The scope of the Determination does not include land based emissions covered by the UNFCCC reporting categories *agriculture* and *LULUCF*. Emissions from fuel combustion for land based industries are, nonetheless, covered by the Determination.

Four estimation methods are provided for under the NGER scheme ranging from low cost simple default methods to higher order methods requiring sampling and analysis of inputs or direct monitoring of emissions.

In general, reporters may choose the estimation method appropriate to their own circumstances. Some important exceptions relate to reporters in the electricity generation, underground coal mining and aluminium industries which are required to use method 2 or higher (see below) for key components of their emissions estimations. These restrictions cover around 60 per cent of emissions reported under the NGER scheme.

The four NGER estimation methods are:

- **NGER Method 1:** is the *National Greenhouse Accounts* default method. Method 1 specifies the use of designated EFs in the estimation of emissions. These EFs are national average factors determined by the Department using the AGEIS. Although significantly updated, this method is very similar in approach to that used by many corporations for over a decade to voluntarily report emissions estimates under the *Greenhouse Challenge Plus* program.

The national inventory only utilises activity data collected from companies that report using this method as no new information is collected in relation to EFs or in relation to other key facility-specific parameters.
- **NGER Method 2:** a facility-specific method using industry sampling and Australian or international standards listed in the Determination or equivalent for analysis of fuels and raw materials to provide more accurate estimates of emissions at facility level. Method 2 enables corporations to undertake additional measurements – for example, the qualities of fuels consumed at a particular facility – in order to gain more accurate estimates for emissions for that particular facility. Method 2 draws on the large body of Australian and international documentary standards prepared by standards organisations in order to provide the benchmarks for procedures for the analysis of, typically, the critical chemical properties of the fuels being combusted. Method 2 was based on existing technical guidelines used by reporters under the *Generator Efficiency Standards* program, which had been in place since 1998.

The national inventory may utilise activity data and EFs or other key facility-specific parameters collected by companies using this method, depending on the analysis of the quality of the data and in accordance with the decision tree set out in section 1.4.1.
- **NGER Method 3:** a facility-specific method using Australian or international standards listed in the Determination or equivalent standards for both sampling and analysis of fuels and raw materials. Method 3 is very similar to method 2, except that it requires reporters to comply with Australian or equivalent documentary standards for sampling (of fuels or raw materials) as well as documentary standards for the analysis of fuels.
- **NGER Method 4:** direct monitoring of emissions systems, either on a continuous or periodic basis. Method 4 provides for a different approach to the estimation of emissions. Rather than providing for the analysis of the chemical properties of inputs (or in some case, products), method 4 aims to directly monitor greenhouse emissions arising from an activity. This approach can provide a higher level of accuracy in certain circumstances, depending on the type of emissions process, however, it is more likely to be more data intensive than other approaches.

As for methods 2 and 3, there is a substantial body of documented procedures on monitoring practices and state and territory government regulatory experience that provide the principal source of guidance for the establishment of such systems.

The national inventory may use emissions data generated using NGER method 4 depending on the analysis of the quality of the data and in accordance with the decision tree set out in section 1.4.1.

Implementation of the NGER (Measurement) Determination

In the thirteenth year of implementation of the NGER scheme (2020–21), 65 per cent of carbon dioxide (CO₂) emissions were estimated using method 2 or 3, i.e. using analysis of carbon content of fuels or other inputs.

By comparison, 35 per cent of CO₂ emissions were estimated using method 1. 0.4 per cent of CO₂ emissions were estimated using method 4 (Figure 1.4). These outcomes reflect choices by companies within the NGER scheme, and reflect the significance of the source and the likely variability in the carbon content of the source. For example, a large majority of emissions from the combustion of coal were estimated using a higher order method. However, method 1 continued to be used principally for petroleum products, which tend to be homogenous in character and for which the payoff from additional measurement effort is often limited. Choices made by companies for gas lay somewhere between coal and petroleum products.

Figure 1.4 2020–21 NGER scheme CO₂ emissions: method selected by NGER reporters

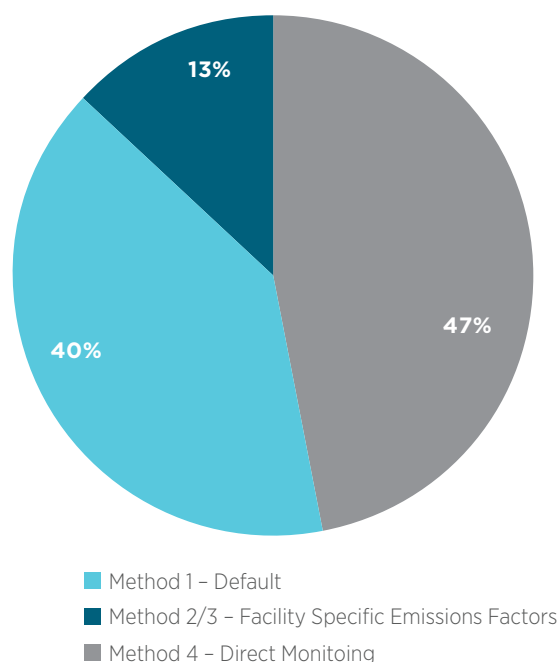

There is a similar story when choices made about estimation methods used for methane are considered (Figure 1.5). Around 47 per cent of CH₄ emissions were estimated using direct monitoring of emissions while 40 per cent of CH₄ emissions were estimated using method 1.

As for CO₂, the choices of the system, and of companies within the system, have resulted in the use of actual measurements from facilities to determine emissions for major sources of CH₄. This outcome relates principally to the choices made by underground coal mines to use directly monitored estimates.

For minor sources of CH₄ and where measurement is difficult, such as CH₄ from combustion of fuels, method 1 has been used by reporting companies under the NGER scheme.

Figure 1.5 2020–21 NGER scheme CH₄ emissions: method selected by NGER reporters

The particular use of this NGER data within the national inventory for each category is explained within their respective chapters of this document.

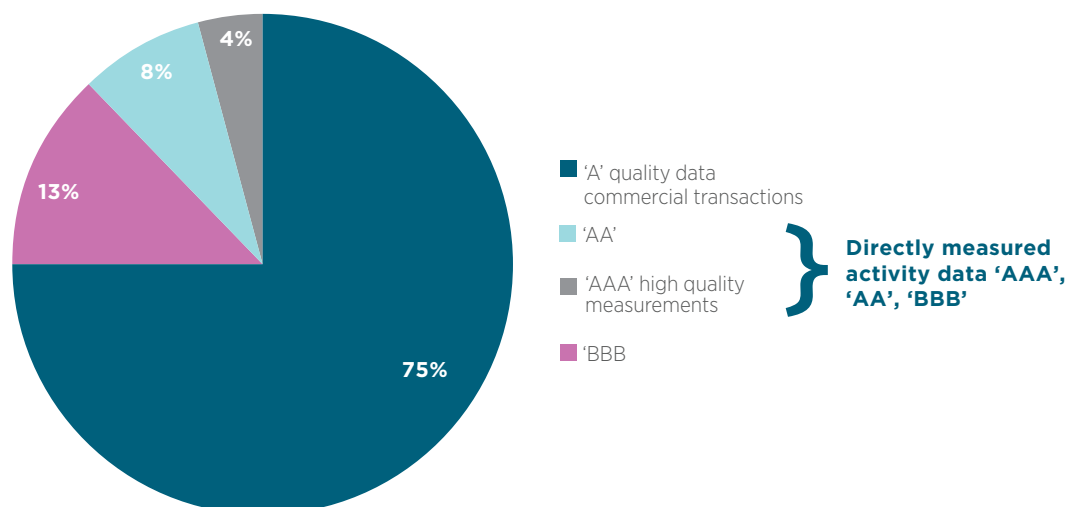

Activity data

The NGER scheme generates activity data on fuel consumption and key activity data inputs in the *industrial processes and product use* and *waste* sectors for NGER reporters. It also aims to maximise the amount of activity data collected from companies that is used for other regulated purposes, including commercial activity and taxation. This approach both reduces the regulatory burden on companies and ensures consistency across national datasets, also formalising the role of the national measurement systems in the national inventory system.

Activity data is rated 'A' if it is estimated using information used to support commercial transactions such as estimates of the amount of fuel purchased. Activity data is rated 'AA' if companies estimate fuel consumed based on information on the amount of fuel purchased and change in stock at the facility. Activity data is rated 'AAA' if companies directly measure fuel consumed using the same tolerance levels for measurement error that govern commercial transactions. In some cases fuel use is not subject to either commercial or taxation activity (i.e. where a facility both extracts and utilises fuel). In these cases, the quality of the data must be signified by a quality rating (i.e. 'BBB'). All 'quality' data is reported by companies as part of their NGER scheme reporting obligations.

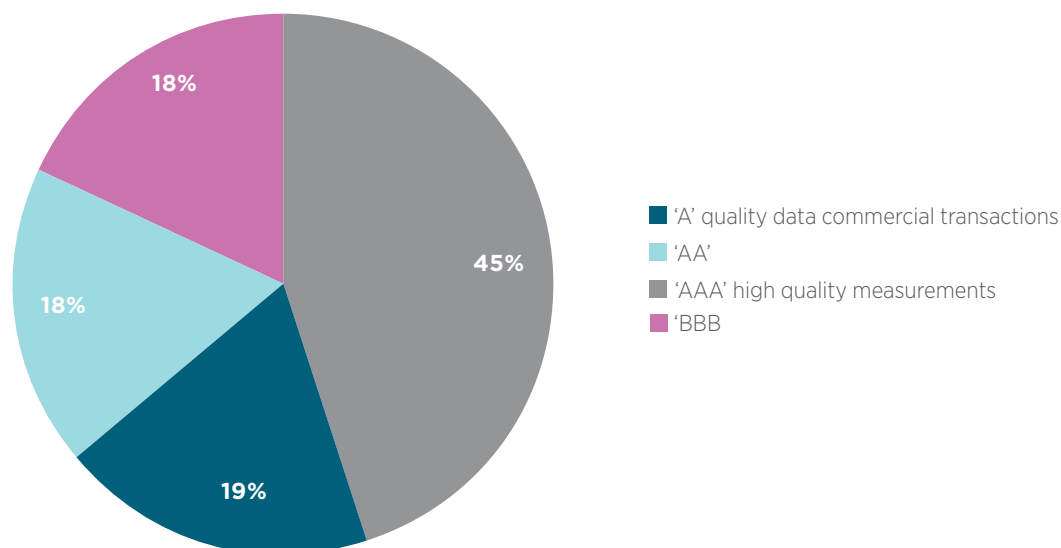

A recent analysis of the choices made by companies with respect to the quality of their activity data inputs is presented in Figure 1.6. Of reported activity data points under the NGER scheme, 75 per cent is derived from commercial transactions and requires no new measurements to be undertaken by the company in order to meet reporting requirements.

Figure 1.6 Activity data selected by NGER reporters by percentage of data points

However, in terms of emissions, companies have tended to choose to use actual measurements of activity to underpin emissions estimates (Figure 1.7). 45 per cent of emissions were estimated using 'AAA' activity data inputs, i.e. estimates of fuel measured at the point of combustion at an accuracy level consistent with standards required to support commercial activity.

Figure 1.7 Activity data selected by NGER reporters by percentage of emissions

It follows that companies have generally used existing commercial data for relatively minor emissions sources. While commercial data accounted for 75 per cent of the data points used in emissions estimation processes, these data points only related to 19 per cent of the estimated emissions.

Use of commercial activity data occurs primarily for gas and petroleum products – often minor sources or where uncertainties associated with the use of data on fuels purchased as a proxy for fuels consumed are considered low. It appears that for major emissions sources, Australian companies have chosen to use the most accurate data

requiring explicit measurement effort while for minor emissions sources they have chosen to use low cost, albeit slightly less accurate data.

NGER scheme data is supplemented where necessary by alternative data sources. Currently national data for the *energy* sector is published in the Department's *Australian Energy Statistics*. *Agriculture* data is obtained by agricultural censuses and surveys conducted by the ABS while *waste* data is principally obtained under State and Territory Government legislation, collected by the DAWE on an annual basis under the National Waste Reporting initiative.

1.5 Brief description of key source categories

A key source category has a significant influence on a country's total inventory of direct greenhouse gases in terms of absolute level of emissions, the trend in emissions, or both. Australia has identified the key categories for the inventory using the tier 1 level and trend assessments as recommended in the IPCC 2006 and adopted by decision 24/CP19. This approach identifies sources that together contribute to 95 per cent of the total emissions or 95 per cent of the trend of the inventory in absolute terms.

When the *LULUCF* sector is included in the analysis, Australia has identified *public electricity (solid fuel)*, *road transportation (liquid fuels)*, and *forest land remaining forest land* as the most significant of the key categories (i.e. contributing more than 10 per cent of the level and/or trend) in 2020. When the *LULUCF* sector is excluded from the analysis the most significant key categories in 2020 are *public electricity (solid fuel)*, *road transportation (liquid fuels)* and *enteric fermentation (cattle)*. More details are provided in Annex 1 of Volume 3 of this Report.

The concept of key categories is also used for choosing the good practice estimation methods for emissions and removals due to activities under Articles 3.3 and 3.4 of the KP. The KP-LULUCF key categories have been identified as outlined in the IPCC 2014. Australia has identified *deforestation, afforestation/reforestation, and forest management, grazing land management and cropland management*, as key categories.

1.6 General uncertainty evaluation

Uncertainty is inherent within any kind of estimation, be it an estimate of the national greenhouse gas emissions, or the national gross domestic product. Managing these uncertainties, and reducing them over time, is recognised by IPCC 2006 as an important element of inventory preparation and development. Uncertainty arises from the limitations of the measuring instruments, sampling processes and the complexity of modelling highly variable sources of emissions over space and time, particularly for some biological sources.

Australia has conducted uncertainty analysis across the sectors of *energy, industrial processes and product use, agriculture, LULUCF* and *waste* in line with IPCC 2006, 2014.

Emissions estimate uncertainties typically are low for CO₂ from energy consumption as well as from some industrial process emissions. Uncertainty surrounding estimates of emissions are higher for *agriculture, LULUCF* and synthetic gases. A medium band of uncertainty applies to estimates from *fugitive emissions, most industrial processes* and non-CO₂ gases in the *energy* sector.

The sectoral estimates presented in Annex 2 of Volume 3 of this Report show that the uncertainty ranges reported for the various components of the Australian inventory are largely consistent with the typical uncertainty ranges expected for each sector, as identified in the IPCC 2006, 2014.

At an aggregate level, using IPCC good practice tier 1 methods, the overall uncertainty surrounding the Australian inventory estimate for 2020 is estimated at ± 5.3 per cent. The reported uncertainty for the trend in emissions

is estimated to be ± 4.7 per cent. When the *LULUCF* sector is excluded from the analysis the uncertainty is estimated at ± 3.1 per cent for the 2020 inventory estimate and ± 3.4 per cent for the trend in emissions.

The IPCC approach provides accurate estimates of uncertainty under certain restrictive assumptions that do not always hold for most countries' inventories. Consequently, the Department is conducting further reviews using available NGER scheme uncertainty data to improve accuracy of the uncertainty estimate for Australia across the sectors of *energy, industrial processes and product use and waste*.

1.7 General assessment of completeness

The inventory is considered to be largely complete with only a few minor sources not estimated, due to either a lack of available information or methodology in the IPCC 2006, 2014. More information on completeness is available in Annex 5. Table 1.6 summarises how completeness is achieved in those categories where NGER data is not solely used to achieve completeness.

Building on the last Report, Australia has prepared additional estimates for the voluntary reporting category of wetlands including emissions for reservoirs and other constructed water bodies, certain ponded pastures, seagrass, tidal marsh removal, as well as for aquaculture and emergence/loss of mangrove forest (reported under forest categories). More information on the coverage of *wetland* categories for this submission is available in Annex 5 of Volume 3 of this Report.

This Report also includes voluntary reporting of additional sources in *fugitive emissions* from post-meter gas appliances and abandoned gas wells, with national methodologies informed by IPCC 2019.

Table 1.6 Summary of data sources used to achieve completeness, where NGER data not sole source, by IPCC category

Category	Source
1.A.1a Electricity (gas)	Completeness is achieved through use of data from the Australian Energy Statistics published by the Department. As explained in section 3.3.2 Methodology – Electricity Generation – Activity Data, the energy use of the small power stations, that do not meet the NGER reporting thresholds, are estimated as the difference between the total of reported values under NGER and DIIS energy statistics for ANZSIC subdivision 26. This approach has been adopted throughout the time series. Therefore the improved coverage of power stations under NGER does not alter the method for estimating total fuel consumption in this sector. Further detail at NIR Volume 1 section 3.3.2.
1.A.1a Electricity (liquid)	As above.
1.A.1c Oil and gas extraction	Completeness is achieved through use of data from the Australian Energy Statistics published by the Department. Further detail in NIR Volume 1 section 3.3.1.
1.A.2 Manufacturing	Completeness is achieved through use of energy balance data, by fuel type and subsector from the Australian Energy Statistics published by the Department. Further detail in NIR Volume 1 section 3.4.1.
1.A.3 Transport	Completeness is achieved through use of national transport fuel sales data published by the Department in the Australian Energy Statistics. Further detail is provided in NIR Volume 1 section 3.5.1.
1.A.4 Other sectors	Completeness is achieved through use of energy balance data, by fuel type and subsector from the Australian Energy Statistics published by the Department. Further detail in NIR Volume 1 section 3.6.1.
1.A.5 Other	This category comprises Military transport only. Completeness is achieved for this source through the use of data obtained directly from the Department of Defence. Further detail in NIR Volume 1 section 3.7.
1.B.2 Oil & Gas	NGER data is complemented by a range of data sources to ensure completeness. Further detail in NIR Volume 1 section 3.9.
2.B.9 Fluorochemical production	Not occurring
3 Agriculture	Completeness is principally achieved through the use of Australian Bureau of Statistics agricultural census data.

Category	Source
4 LULUCF	Completeness is principally achieved through the application of annual wall-to-wall spatial monitoring changes in woody vegetation cover. Completeness is achieved through use of energy balance data, for combusted harvested wood products, from the Australian Energy Statistics published by the Department.
5.A Solid waste	Completeness for solid waste disposal is discussed in NIR Volume 2 Chapter 7 of the NIR. NGER data cover about 70 per cent of total waste disposal in Australia. Solid waste disposal data is also provided by the Stewardship Waste Section of the Department of Agriculture, Water and the Environment, which collects disposal data from each State and Territory annually as part of the National Waste Reporting initiative. The residual disposal not covered by the NGER scheme is calculated as the total disposal reported for each state and territory minus the sum of NGER disposal in each State and Territory. Figure 7.4 of NIR Vol 2 shows the relationship between State and Territory reported disposal and disposal reported under the NGER scheme. Methane capture data obtained under the NGER scheme are considered complete as they are supplied by gas capture companies (as distinct from landfill operators) all of which trigger reporting thresholds of the NGER scheme.
5.B Biological treatment of solid waste	Emissions estimates are based on an annual industry survey undertaken by the Recycled Organics Unit at the University of NSW. Refer to Chapter 7 of volume 2 of the NIR for further information.
5.C Waste incineration	Data on the quantities of municipal solid waste incinerated are based upon published processing capacities of the three incineration plants prior to decommissioning in the mid-90s. Data on the quantities of clinical waste incinerated have been obtained from a per-capita waste generation rate derived from data reported under the NGER scheme, by O'Brien (2006b) and an estimate of State population reported by the Australian Bureau of Statistics. Refer to Chapter 7 of volume 2 of the NIR for further information.
5.D.1 Domestic and commercial wastewater	Major wastewater treatment facilities report under the NGER Scheme. NGER reporting requirements include the population serviced by each treatment plant. Population data and per-capita wastewater organic matter and N generation rates are used to determine the residual. Refer to Chapter 7 of volume 2 of the NIR for further information.
5.D.2 Industrial wastewater	Where appropriate, national commodity production statistics are used to ensure completeness of AD for industrial wastewater. Refer to Chapter 7 of volume 2 of the NIR for further information.

1.7.1 Geographical coverage

The Australian inventory covers the six states (New South Wales, Victoria, Queensland, South Australia, Western Australia and Tasmania), the mainland territories (Northern Territory, Australian Capital Territory and Jervis Bay Territory) and the associated coastal islands.

The geographical coverage of the Australian inventory also includes emissions from the following external territories:

- Norfolk Island
- Christmas Island
- Cocos Islands
- Heard and McDonald Islands

Australia's Antarctic Program operations in the Antarctic are also covered.

The following external territories are also covered are included in the state statistical territories by the ABS:

- Coral Sea Islands (Queensland); and
- Ashmore and Cartier Islands (Northern Territory).

The coverage of emissions/removal categories for the external territories is as follows:

- *fuel combustion*, *waste* and HFC emissions associated with refrigeration are estimated;
- *fugitive emissions* and *industrial processes and product use* emissions are assumed to be not occurring; and
- *agriculture* and *LULUCF* emissions and removals are not estimated but are likely to be negligible.

2. Trends in emissions

2.1 Emission trends for aggregated greenhouse gas emissions

Australia's total greenhouse gas emissions in 2020 were 487.6 Mt CO₂-e (Table 2.1 and Figure 2.1). This represents a decrease of 138.7 Mt CO₂-e (-22.1 per cent) on net emissions recorded in 1990.

Table 2.1 National greenhouse gas emissions, Mt CO₂-e

UNFCCC classification sector and subsector	Emissions Mt CO ₂ -e						Per cent change
	1990	2005	2010	2015	2019	2020	2005–2020
1 Energy (combustion + fugitive)	293.7	400.1	418.4	418.7	431.2	415.5	3.8
Stationary energy	195.5	278.9	288.2	279.0	278.8	272.4	- 2.3
Transport	61.4	82.2	88.8	95.4	100.3	93.5	13.7
Fugitive emissions from fuel	36.8	39.0	41.4	44.3	52.0	49.6	27.4
Carbon capture and storage						0.01	N/a
2 Industrial processes and product use	25.9	30.7	34.1	31.1	33.4	32.7	6.6
3 Agriculture	84.9	79.8	69.8	73.6	69.8	67.8	- 15.0
4 Land use, land use change and forestry incl. natural disturbances provision	200.6	83.8	66.4	2.9	-40.4	-40.1	- 147.9
6 Waste	21.1	14.3	14.6	11.6	11.9	11.7	- 17.9
Total net emissions	626.3	608.6	603.2	537.8	505.8	487.6	- 19.9
Memo: Total net emissions without natural disturbances provision	623.0	578.3	588.9	526.6	531.7	1,257.7	117.5

These estimates, and preliminary estimates for 2021, are also presented in Annex 3, Volume 3 of this Report using the emissions metric adopted under the Paris Agreement – 100 year time horizon GWP values from the IPCC Fifth Assessment Report.

To ensure transparency, and consistent with Paris Agreement decision 18/CMA.1, Table 2.1 also presents total net emissions without the application of the natural disturbance provision. Australia's approach to addressing emissions and subsequent removals from natural disturbances is detailed in Chapter 6, Volume 2, and summarised in section ES.3.1, Volume 1, of this Report.

The 2020 emissions above include net emissions from natural disturbances during the 2019–2020 fire season noting that affected forests are expected to recover over time, generating a significant carbon sink in the coming years. As forests recover, reporting without the natural disturbances provision's application would reduce national emissions by 144 Mt CO₂ in 2021, and recovery from past disturbances is forecast to contribute a net sink of 701 Mt CO₂ over the decade to 2030. The future recovery of the forest is expected to be complete, so the 2019–20 bushfires are expected to have a negligible impact on the long-run trend in carbon stock change in the affected forests.⁸ The department will actively monitor the forest recovery from the bushfires to ensure that any future human disturbances, such as salvage logging, future fire disturbance and the impacts of changes in climate are taken into account.

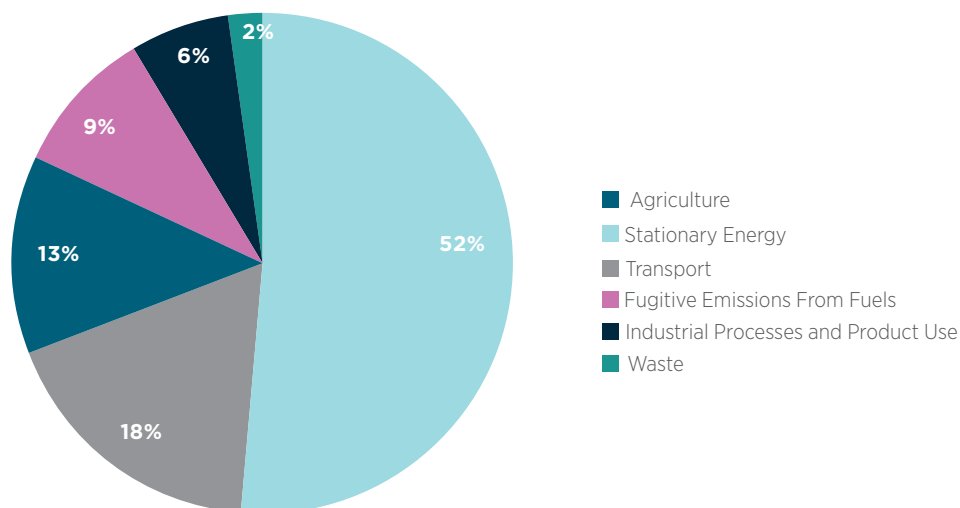

⁸ <https://www.industry.gov.au/bushfirereport>

Figure 2.1 National Inventory trend for aggregated greenhouse gas emissions (including LULUCF), Australia, 1990–2020

The combined *energy* subsectors (including *stationary energy*, *transport* and *fugitive emissions*) were the largest source of greenhouse gas emissions in 2020 comprising 78.7 per cent of emissions excluding *LULUCF* (Figure 2.2) followed by the *agriculture* sector (12.9 per cent).

Figure 2.2 Contribution to total net CO₂-e emissions (excluding LULUCF) by sector, Australia, 2020

2.2 Emissions trends per capita and per GDP

Australia's emissions per capita and per dollar of gross domestic product (GDP) have generally declined over the last twenty years. These declines have resulted from specific emissions management actions across sectors, the large decline in land use change emissions over the period, and structural changes in the economy.

Australia's population grew strongly between 1990 and 2020, from 17.1 million in 1990 to around 25.7 million in 2020 (growth of 50.5 per cent). For the national inventory total (including emissions from the land sector), the 2020 estimate is 19.1 t CO₂-e per person, compared to 36.9 t CO₂-e in 1990 (Figure 2.3), representing a 48.4 per cent decline.

Figure 2.3 Emissions per capita, Australia (t CO₂-e per person)

Australia's GDP (chain volume measures) also grew over this period, from 838 billion Australian dollars (AUD) in 1990 to around AUD 1,981 billion in 2020 (growth of 136.4 per cent). For the national inventory total (including emissions from *LULUCF*), the 2020 estimate is 0.26 kg CO₂-e per dollar, compared to 0.75 kg CO₂-e per dollar in 1990 (Figure 2.4), which is a decline of 65.4 per cent.

Figure 2.4 Emissions per GDP, Australia (kg CO₂-e per dollar of real GDP 2020–21 prices)

2.3 Emissions trends by sector

Sectors with increasing emissions over the 1990 to 2020 period included *stationary energy* (39.3 per cent), *transport* (52.2 per cent), *fugitive emissions from fossil fuels* (34.9 per cent) and *industrial processes and product use* (26.4 per cent). Decreased emissions were recorded for *waste* (44.5 per cent), *agriculture* (20.1 per cent) and *LULUCF* (120.0 per cent).

Figure 2.5 shows the emissions for each sector from 1990–2020. The principal drivers of these emissions trends are as follows:

- **Energy:** The largest sectoral increase in greenhouse gas emissions over the 1990 to 2020 period, of 76.9 Mt CO₂-e (39.3 per cent), occurred in the stationary energy sector, driven in part by increasing population, household incomes and export increases from the resource sector. Emissions from the public electricity and heat production sub-sector in 2020 decreased by 39.7 Mt CO₂-e (18.7 per cent) from the peak in 2009, despite continuing population and economic growth. This was primarily driven by a 13.1 per cent decrease in the share of generation from coal, along with a 12.8 per cent increase in the share of generation of renewable energy in the National Electricity Market, with the largest increases coming from wind and solar. The main drivers for the increase in transport emissions are continuing growth in the number of passenger vehicles, along with an increase in diesel consumption in heavy vehicles and an increase in air travel. Fugitive emissions have increased over the period largely due to increased production from open cut coal mines and increased gas production. The most recent increase, since 2015, is associated with an expansion of LNG exports; annual LNG production increased 41 per cent in 2017 and 21 per cent in 2019. LNG production grew 6 per cent in 2020.
- **Industrial processes and product use:** The emissions in the industrial processes and product use sector have increased by 26.4 per cent since 1990. The increase is primarily driven by the growth in the bank of hydrofluorocarbons (HFCs) used in refrigeration and air-conditioning equipment (which replaced ozone depleting chemicals phased out by the Montreal Protocol). Increased HFC emissions over the period from

refrigeration and air conditioning were partly offset by declining emissions in other activities, in particular, in metals production. Declines in emissions from iron and steel production have been observed due to plant closures while declines in emissions from aluminium production are largely due to improvements in process control and plant upgrades and closures.

- *Agriculture*: Agricultural emissions have decreased by 20.1 per cent since 1990. Climate (droughts, recovery from droughts, large seasonal differences, rainfall and floods) as well as economic forces (national and international markets and produce demand) directly impact emissions from the agricultural sector. The decline is primarily associated with a decline in sheep numbers as a result of the wool crisis and the collapse of the wool reserve price scheme. From 1995 to 2000 emissions increased due to increased beef cattle numbers and crop production, which resulted most markedly in increased enteric fermentation emissions and increased emissions from agricultural soils. From 2000 until 2010, prolonged and widespread drought conditions over southern and eastern Australia contributed to reductions in livestock populations, crop production, and fertiliser use. In turn, emissions declined over this period. As Australia saw relief from the Millennium Drought, emissions rose between 2011 and 2017, as farmers were able to increase herds and flocks and crop production. Drought conditions in more recent years have resulted in a lack of feed and elevated levels of turn-off of cattle and sheep and a contraction in the livestock population. In addition, crop production and fertiliser consumption has decreased. Decreases in emissions have followed.
- *Waste*: Emissions from the waste sector have decreased by 44.5 per cent, as increases in waste generation associated with growing populations and industrial production have been offset by increased methane recovery. The majority of emissions were from solid waste disposal (72.6 per cent), which has experienced a substantial improvement in methane recovery rates over the period (from a negligible amount in 1990 to 8.4 Mt CO₂-e in 2020).
- *LULUCF*: The decrease in emissions from LULUCF since 1990 (-120.0 per cent) has been mainly driven by the decline in emissions from land clearing (forest land converted to other land uses), forest cover expansion (including post-1990 plantation establishment), and declines in the harvesting of native forests.

Trends in emissions from each sector are discussed further in Chapters 3–7.

Figure 2.5 Net CO₂-e emissions by sector, Australia, 1990–2020

2.4 Analysis of emissions trend drivers

Kaya analysis

The following kaya analysis demonstrates that growth in population and gross domestic product have placed upward pressure on national carbon dioxide emissions, offset by decreases in energy intensity and, to a lesser extent, emissions intensity.

An equation based on the Kaya identity (Equation 2.1) expresses CO₂ emissions from fuel combustion and industrial processes and product use (IPPU) as the product of four factors: population; GDP per capita; the energy intensity of the economy and the emissions intensity of energy.

$$\text{Equation 2.1: CO}_2 \text{ from fuel combustion and IPPU} = P \times \frac{\text{GDP}}{P} \times \frac{\text{Energy}}{\text{GDP}} \times \frac{\text{CO}_2}{\text{Energy}}$$

Where P = Population

GDP = Gross domestic product

Energy = Total net energy consumption

CO₂ = CO₂ emissions from fuel combustion and IPPU

Trends in these factors provide insight into how Australia's national circumstances have impacted on CO₂ emissions since 1990. However, it should be noted that each factor is not necessarily independent of each other (i.e. increases in GDP per capita may change the energy intensity of the economy) and an increase in a single

factor will not automatically result in a corresponding change in CO₂ emissions (i.e. an increase in population does not automatically result in an equivalent increase in CO₂ emissions).

Between 1990 and 2020, CO₂ emissions from fuel combustion and IPPU increased by 41 per cent (Figure 2.6). Underlying growth factors were a 51 per cent increase in population and a 57 per cent increase in GDP per capita. Declining factors were a 35 per cent decline in the energy intensity of the economy and an 8 per cent decline in the emissions intensity of energy consumption. Over the time series, Australia's CO₂ emissions trended upwards until 2009 before declining over the period to 2020 as the impact of improved energy intensity of the economy and emissions intensity of energy supply more than offset increases in population and GDP per capita.

Figure 2.6 Growth in CO₂ emissions from fuel combustion and IPPU and underlying drivers, Australia, 1990–2020

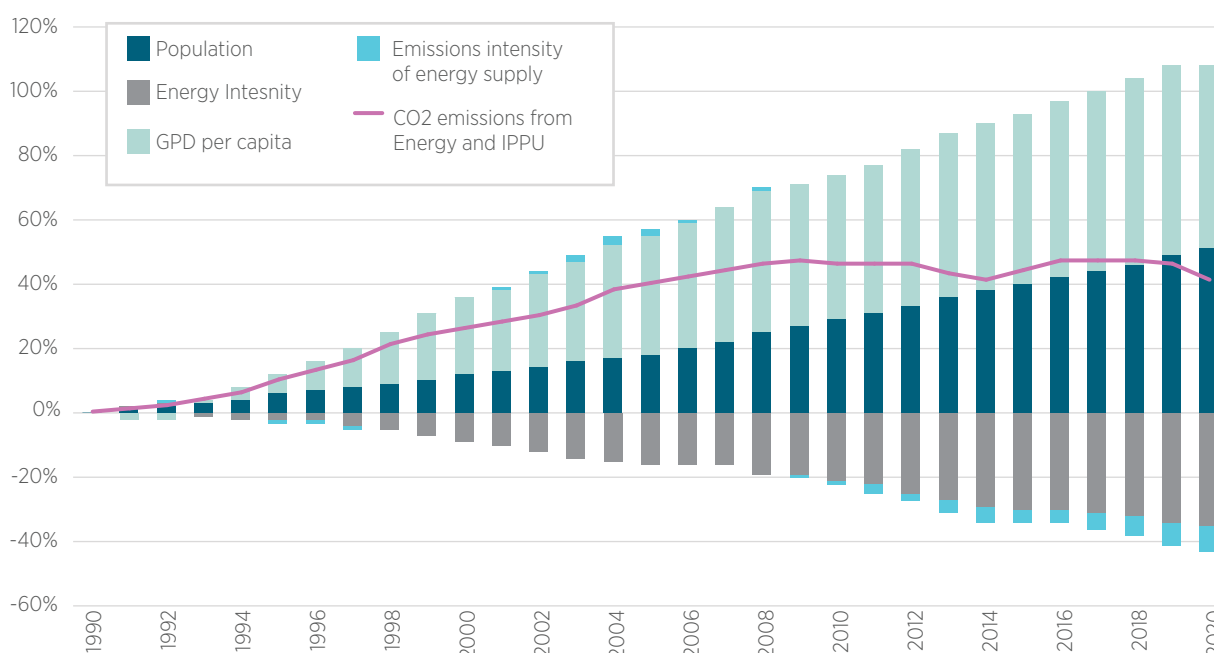

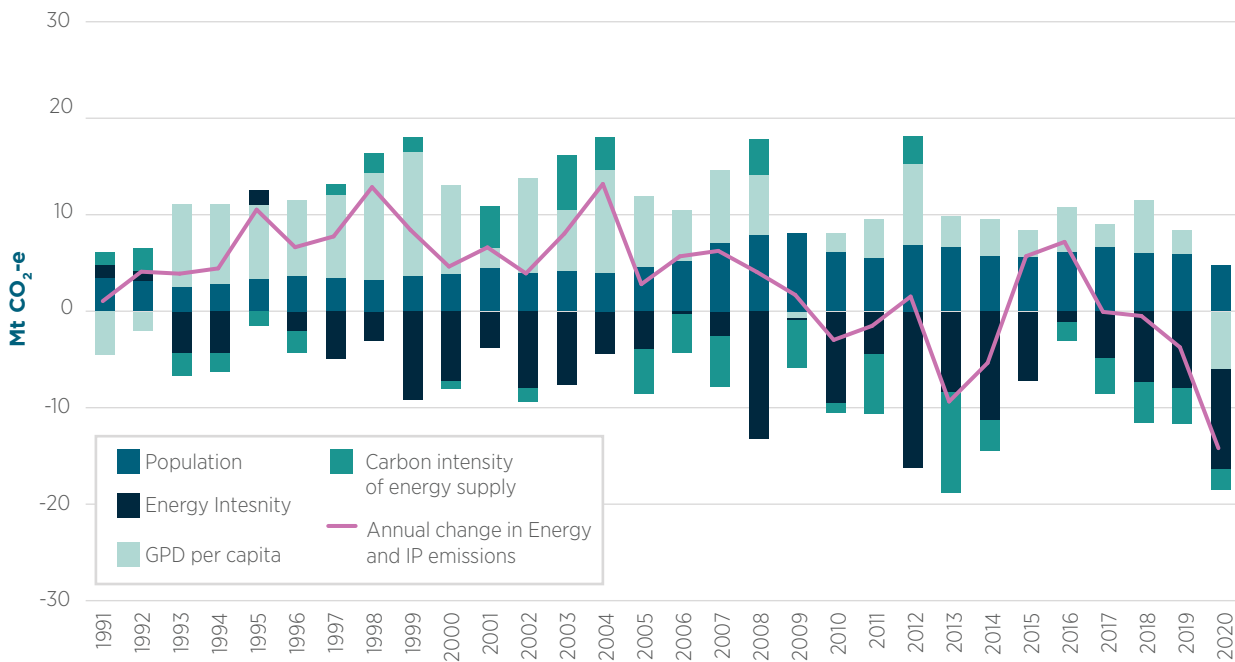

Figure 2.7 attributes annual emissions changes to the four underlying factors. The combined impact of increases in population and GDP per capita have contributed to increasing emissions since 1990.

Like many other regions, Australia's economic activity was impacted by COVID-19 in 2020. GDP per capita fell by 1.5 per cent in 2020 (the first fall in GDP per capita since 1991), in addition there was a 3.5 per cent decrease in fuel combustion, and the rate of population growth declined from 1.5% in 2019 to 1.3% in 2020. These factors drove a 3.2 per cent reduction in CO₂ emissions from energy and IPPU.

The energy intensity of the economy decreased in 27 of the 30 years at varying annual rates reflecting energy efficiency improvements and structural change in the economy towards less energy intensive service sectors. The emissions intensity of energy supply (grey bar) has fluctuated over the time series however there has been a declining trend since 2005 as the proportion of electricity generation from coal has declined.

Figure 2.7 Annual change in CO₂ emissions from fuel combustion and IPPU from underlying drivers: Australia 1991–2020 (Mt CO₂-e)

This trend is reflected in the fuel switching evident in the observed choice of fuel for energy consumption (Figure 2.8). Over the period 1990–2009 consumption of coal, oil and natural gas (for fuel combustion) increased. From 2009, oil and gas consumption continued to grow, driven by the *transport* and *electricity* sectors. In contrast coal consumption declined since that time. In 2020, coal consumption was 26.6 per cent below its 2009 peak level of 2,414 petajoules, and oil consumption fell 6.7 per cent compared to 2012 levels, largely driven by reduced use in the transport sector during COVID-19.

Figure 2.8 Energy consumption by fuel type 1990–2020 (PJ)

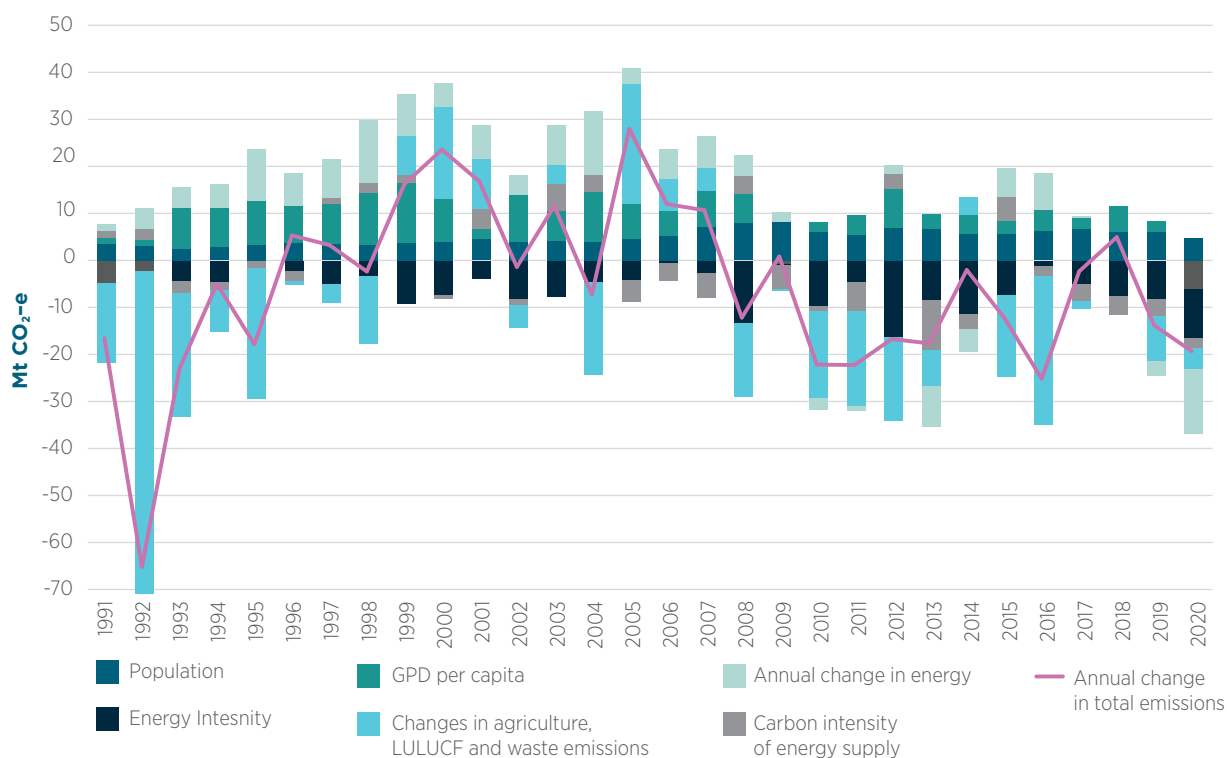

Source: Australian Energy Statistics 2021 Update, Table D

The Kaya analysis considers a subset of Australia's total emissions. At the national level increases in CO₂ emissions from fuel combustion and IPPU have been offset by declines in other emissions sources. Figure 2.9 expands the decomposition to include other emissions sources as a fifth driver of total emissions (equation 2.2). This analysis does not attempt to break down other emissions into underlying drivers such as energy consumption, population or GDP growth which have less of an effect on these types of emissions.

CO₂-e emissions from fuel combustion and IPPU fell by 3.5 per cent in 2020 compared to 2019, or by 4.7 per cent on a per capita basis. Similarly, carbon intensity improved by 0.6 per cent.

Changes in other emissions sources generally have a downward impact on total emissions; however, annual changes are subject to considerable variation.

Figure 2.9 Annual change in total emissions from underlying drivers: Australia 1991–2020 (Mt CO₂-e)

2.5 Emissions trends for Kyoto Protocol - LULUCF inventory

This section contains emissions and removals associated with Articles 3.1, and 3.4 of the KP for CP2. (Table 2.2)

Under the KP accounting rules, Parties must report emissions from the *energy, industrial processes and product use, agriculture and waste* sectors as well as the *deforestation* activity from the *LULUCF* sector. For the CP2, Australia accounts for the mandatory activities *afforestation/reforestation* and *forest management* and the voluntary activities *cropland management, grazing land management* and *revegetation*. Australia does not account for *wetland drainage and rewetting* for the CP2.

In the final year of CP2, 2020:

- The *deforestation* activity contributed net emissions of 26.1 Mt CO₂-e in 2020. Under KP accounting rules this estimate would lead to the cancellation of Assigned Amount Units (AAUs) equivalent to this amount.
- Under KP accounting rules, the *afforestation/reforestation* activity is estimated to generate RMU credits equivalent to 17.0 Mt CO₂-e in 2020.
- *Forest management, cropland management, grazing land management* and *revegetation* activities are estimated to generate RMU credits of 64.1 Mt CO₂-e in 2020.

Further detail on the *LULUCF* activities is provided in Chapter 11 of Volume 3. Information on holdings and transactions of Kyoto units in the financial year 2020–21, is provided in Chapter 12 of Volume 3.

Table 2.2 Emissions and removals associated with Articles 3.1, 3.3 and 3.4 of the Kyoto Protocol, 2013–2020

Sector and subsector	Emissions Mt CO ₂ -e							
	2013	2014	2015	2016	2017	2018	2019	2020
Energy	414.1	408.1	418.7	428.1	430.2	432.6	431.2	415.5
IPPU	30.2	30.1	31.1	31.2	31.8	32.6	33.4	32.7
Agriculture	76.0	76.4	73.6	72.6	76.6	75.1	69.8	67.8
Waste	12.1	12.0	11.6	12.1	12.3	12.2	11.9	11.7
Deforestation (a)	38.6	42.2	33.4	32.8	31.9	34.6	25.7	26.1
National inventory emissions (1)	570.9	569.0	568.3	576.8	582.7	587.1	571.9	553.8
RMU credits generated by Article 3.3 and 3.4 activities								
Afforestation/reforestation (a)	-23.8	-24.2	-24.0	-26.8	-28.1	-19.9	-16.1	-17.0
Article 3.4 activities	-36.9	-29.7	-40.1	-63.2	-66.9	-63.7	-70.7	-64.1
Total RMU credits (2) (b)	-60.6	-53.9	-64.2	-90.0	-95.0	-83.6	-86.9	-81.1
Kyoto Protocol Total (1 – 2)	510.2	515.0	504.1	486.8	487.8	503.5	485.0	472.7

(a) Australia has elected to account for Article 3.3 activities on an annual basis, and Article 3.4 activities at the end of CP2.

(b) Accounting quantity in accordance with decisions 2/CMP.7 and 3/CMP.11 and estimates for Cropland Management and Grazing Management were adjusted for the emissions reported under Forest Conversion in the UNFCCC in 1990 for conversions up to 31 December 1989, and recorded in the report used to calculate the assigned amount, in order to avoid double counting.

3. Energy

3.1 Overview

Total emissions from the *energy* sector for 2020 were estimated to be 415.5 Mt CO₂-e (Table 3.1). *Energy industries* were the main contributor, accounting for 50.0 per cent of emissions from the *energy* sector. Other significant contributors to total *energy* emissions were *transport* (22.5 per cent), and *manufacturing industries and construction* (9.9 per cent).

Energy sector emissions increased by 41.5 per cent between 1990 and 2020. Annual emissions from 2019 to 2020 decreased by 15.7 Mt (3.6 per cent).

Table 3.1 Energy sector CO₂-e emissions, 2020

Greenhouse Gas Source and Sink Categories	CO ₂ -e emissions (Gg)			Total 2020 CO ₂ -e
	CO ₂	CH ₄	N ₂ O

4 Other sectors	21,446	876	194	22,516
5 Other Mobile (military)	939	1	8	948
B. Fugitive emissions from fuels	17,273	32,275	68	49,616
1 Solid fuels	2,381	25,176	1	27,558
2 Oil and natural gas	14,892	7,100	67	22,059
C. CO₂ Transport, Injection and Geological Storage	12	0	0	12
1 Injection and storage	12	0	0	12
2 Transport	0	0	0	0

Trends in fuel consumption use within the *Energy* sector are shown in Figure 3.1. A slowdown in the consumption of solid fuels is accompanied by continuing increases in gaseous and liquid fuel use.

Figure 3.1 Energy sector CO₂-e emissions by fuel type, percentage change since 1990

3.1.1 Stationary energy

Stationary energy principally comprises fossil fuel combustion in *energy industries* and *manufacturing industries and construction*. Total estimated emissions from stationary energy combustion were 272.4 Mt CO₂-e in 2020, equal to 51.6 per cent of net national emissions (excluding *LULUCF*).

The *energy industries* subsector includes fuel combustion in electricity generation, petroleum refining, gas production and solid fuel manufacture. *Electricity and heat production* (1.A.1.a) contributed 172.0 Mt CO₂-e or 63.1 per cent of *stationary energy* emissions in 2020. This category includes emissions only from electricity generation because heat production as defined by the IPCC does not occur in Australia. Estimated emissions from the remaining *energy industries* subsectors were 35.6 Mt CO₂-e in 2020.

The *manufacturing industries and construction* subsector (1.A.2) emissions were 41.3 Mt CO₂-e in 2020. This subsector includes direct emissions from fuel combustion in manufacturing industries, ferrous and non-ferrous metals production, plastics production, construction and non-energy mining. These calculations do not fully reflect the greenhouse impact of these industries, as the emissions generated from the production of electricity used in these industries are included under *electricity and heat production* (1.A.1.a).

Estimated emissions from *other sectors* (1.A.4) were 22.5 Mt CO₂-e in 2020. This subsector comprises direct fuel combustion in the residential, commercial and institutional sectors, including energy used in mobile equipment in *agriculture, forestry* and *fishing* industries. However, as with *manufacturing*, much of the greenhouse impact of these sectors arises from their large consumption of electricity, which is not reflected in this figure alone (reported under 1.A.1.a). *Other* (1.A.5) comprises of emissions from *military transport* (0.9 Mt CO₂-e).

Trends

Emissions from *stationary energy* increased by 39.3 per cent (76.9 Mt CO₂-e) between 1990 and 2020, including an increase in emissions from the combustion of solid fossil fuels of 12.0 per cent (15.8 Mt CO₂-e) in the same period (Figure 3.2). Emissions related to gaseous fossil fuels have shown the largest relative and absolute growth, increasing by 141.1 per cent (47.1 Mt CO₂-e) between 1990 and 2020. Emissions from liquid fossil fuels increased by 56.4 per cent (15.4 Mt CO₂-e) in the same period. Biomass emissions decreased by 54.9 per cent (1.5 Mt CO₂-e) between 1990 and 2020. Between 2019 and 2020, emissions from *stationary energy* decreased by 2.3 per cent (6.4 Mt CO₂-e).

Figure 3.2 Total CO₂-e emissions from stationary energy combustion by fuel, 1990–2020

Electricity generation emissions decreased by 7.3 Mt (4.1 per cent) from 2019 to 2020, and increased by 42.4 Mt (32.7 per cent) from 1990 to 2020 (Figure 3.3). From 2019 to 2020 there were decreases in emissions from black coal of 5.5 per cent and brown coal of 4.6 per cent and an increase for gaseous fuel of 2.8 per cent.

Figure 3.3 CO₂-e emissions from electricity generation by fossil fuels, 1990–2020

Emissions from *stationary energy* subsectors, other than *electricity generation*, increased by 0.8 Mt CO₂-e (0.8 per cent) between 2019 and 2020, and increased overall by 34.5 Mt (52.3 per cent) from 1990 to 2020.

Emissions from the *manufacturing industries and construction* subsector increased by 0.2 per cent (0.1 Mt CO₂-e) between 2019 and 2020 and increased by 14.0 per cent (5.1 Mt CO₂-e) from 1990 to 2020.

3.1.2 Transport

In 2020, the *transport* sector contributed 93.5 Mt CO₂-e or 17.7 per cent of Australia's net emissions (excluding *LULUCF*).

The major source of *transport* emissions in Australia is road transportation, which accounts for 85.4 per cent (79.8 Mt CO₂-e) of *transport* emissions. This outcome is principally driven by the importance of motor vehicles as modes of transportation for passengers and freight in Australia. Passenger cars account for 40.9 Mt CO₂-e and trucks (light and heavy) and buses 21.8 Mt CO₂-e. Other sources are far smaller – domestic aviation contributed 7.1 per cent (6.6 Mt CO₂-e), domestic navigation 2.2 per cent (2.0 Mt CO₂-e), railways 4.2 per cent (4.0 Mt CO₂-e) and pipeline transport 1.0 per cent (1.0 Mt CO₂-e).

Fuel used in *international transport* (*international aviation* and *marine 'bunkers'*) is by international agreement reported separately from the national total net emissions. In 2020, international bunker fuels generated 13.9 Mt CO₂-e of emissions.

Figure 3.4 Total transport emissions, 1990–2020

Trends

Transport emissions are one of the strongest drivers in Australia's emissions. Emissions from this sector were 52.2 per cent (32.1 Mt CO₂-e) higher in 2020 than in 1990, and on average have increased by around 1.4 per cent annually (Figure 3.4).

Emissions from passenger cars increased by 17.4 per cent (6.1 Mt CO₂-e) since 1990, but have decreased by 9.4 per cent (4.3 Mt CO₂-e) since 2019. Emissions from light commercial vehicles (LCVs) and heavy duty trucks and buses have also grown strongly (126.8 per cent and 91.1 per cent respectively) over the same period. Emissions from pipeline transport grew very strongly between 1990 and 2020, increasing 267.1 per cent (0.7 Mt CO₂-e).

Impact of COVID-19 Pandemic on Emissions from Transport sector

The COVID-19 pandemic had a strong effect on Australia's transport sector emissions and liquid fuel consumption in 2020. Emissions from transport sector fell by 6.8 per cent (6.9 Mt CO₂-e) overall on 2019.

Between 2019 and 2020, road transport petrol consumption declined by 11.4 per cent (67.2 PJ) while diesel consumption remained relatively steady. The emissions reduction from passenger cars (9.4 per cent or 4.3 Mt CO₂-e) contributed significantly to the decline in road transport.

Emissions from domestic aviation also declined by 21.6 per cent (1.8 Mt CO₂-e) due to a 21.7 per cent reduction in Jet fuel consumption (25.9 PJ) reflecting COVID-19 pandemic related travel restrictions. Transport remained the second largest contributor to Australia's emissions despite the reduced activity.

Long term trends

Since 1990, domestic passenger air travel grew by 346 per cent (measured in available seat km – ASK), driving a 153.2 per cent increase in emissions (4.0 Mt CO₂-e). This increase is associated with population growth and cheaper airfares offered by budget airlines.

However, due to the COVID-19 pandemic, ASK declined by 25 per cent in 2020 on 2019 which has seen a 21.6 per cent (1.8 Mt CO₂e) reduction in emissions.

Emissions from pipeline transport increased by 21.5 per cent between 2005 and 2020. This is due to increased throughput associated with the expansion of gas production, especially offshore production.

Increase in diesel consumption in road transport and passenger vehicles

The Australian Energy Statistics data shows that between 2005 and 2020, diesel consumption in total road transport grew by 84 per cent (280 PJ) while petrol consumption declined by 17 per cent (109 PJ).

In the same period, diesel consumption by passenger vehicles grew by 184 per cent while petrol consumption fell by 13 per cent (Figure 3.5).

Figure 3.5 Energy consumption in road transport by fuel type (2005–2020)

Increase in market share of Sport Utility Vehicles (SUV)

Since 2005, SUV sales are up by 151 per cent while traditional passenger vehicle (PV) sales decreased by 64 per cent (Figure 3.6).

Figure 3.6 SUV and passenger vehicles sales trend in Australia, 2005–2020

3.1.3 Fugitive emissions

Total estimated *fugitive emissions* for 2020 were 49.6 Mt CO₂-e, representing 9.4 per cent of net national emissions (excluding LULUCF). Net *solid fuel* emissions contributed 55.5 per cent (27.6 Mt CO₂-e) of *fugitive emissions*. *Oil and natural gas production, processing and distribution* account for the remaining 44.5 per cent (22.1 Mt CO₂-e) of *fugitive emissions*.

Trends

Overall *fugitive emissions* increased 34.9 per cent (12.8 Mt CO₂-e) between 1990 and 2020, and decreased by 4.7 per cent (2.4 Mt CO₂-e) from 2019 to 2020 (Figure 3.7). From 1990 to 2020, *fugitive emissions* from *solid fuels* increased by 20.0 per cent (4.6 Mt CO₂-e) and *oil and natural gas* emissions increased by 59.7 per cent (8.2 Mt CO₂-e).

Figure 3.7 CO₂-e fugitive emissions by category, 1990–2020

Fugitive emissions from solid fuels increased by 4.1 per cent (1.1 Mt CO₂-e) between 2019 and 2020. Underground mine emissions increased by 7.2 per cent (1.2 Mt CO₂-e). Emissions from surface mines decreased by 3.7 per cent (-0.3 Mt CO₂-e) between 2019 and 2020. Emissions from decommissioned mines have decreased by 16.0 per cent (-0.1 Mt CO₂-e) between 2019 and 2020, and emissions from flaring increased by 54.3 per cent (0.4 Mt CO₂-e).

Emissions tend to fluctuate from year to year depending on the volume of coal mined and the share of production from underground mines of varying gas contents. Mine production of coal has increased from 241.0 Mt in 1990 to 604.8 Mt in 2020, an increase of 150.9 per cent. Methane emissions have not grown as fast as activity principally because, since 1998, there has been an increasing trend in activity from surface mines, which emit less gas than underground mines due to their shallower depth, compared with that of underground mines (Figure 3.8). Within underground mines, a decreasing share of production from the gassiest southern coal field. In addition, the flaring of pre-drainage gas and technologies to recover and utilise coal mine waste gas for electricity generation have been increasingly adopted in underground mining, particularly in recent years.

Figure 3.8 Fugitive CO₂-e emissions from coal mining activities, 1990–2020

Oil and natural gas fugitive emissions increased 59.7 per cent (8.2 Mt CO₂-e) between 1990 and 2020 (Figure 3.9) while production increased 240.4 per cent during the same time period. The reduction in emissions intensity for this sector is driven by improvements in gas distribution (a reduction of 76.6 per cent in emissions since 1990) and large and efficient production, processing, and export facilities coming online (LNG).

Between 1990 and 2020, fugitive emissions from oil-related activities decreased 63.8 per cent (0.3 Mt CO₂-e) whereas emissions from gas-related activities have decreased 1.8 per cent (-0.1 Mt CO₂-e). Between 2019 and 2020, emissions from oil-related activities decreased 0.3 per cent (-0.0005 Mt CO₂-e) whereas emissions from gas-related activities have increased 4.6 per cent (0.2 Mt CO₂-e).

Emissions from venting decreased 13.1 per cent (-1.5 Mt CO₂-e) in 2020 when compared with 2019, and increased 145.8 per cent (5.9 Mt CO₂-e) compared with 1990. Flaring emissions decreased 24.6 per cent (-2.2 Mt CO₂-e) in 2020 when compared with 2019, and increased 64.7 per cent (2.7 Mt CO₂-e) since 1990.

The 18.2 per cent (-3.7 MtCO₂-e) fall in venting and flaring emissions in 2020 compared to their historic peak in 2019 was driven largely by the first full year of injection at the Gorgon Carbon, Capture and Storage (CCS) project.

Gorgon also reported fugitive emissions from the injection of CO₂ into geological storage for 2020, with 0.01 Mt of CO₂ emissions associated with the injection of 2.7 Mt CO₂ into geological storage.

Figure 3.9 Fugitive CO₂-e emissions from oil and gas production, 1990–2020

3.2 Overview of source category description and methodology - energy

The *energy* sector includes emissions from the combustion of fossil fuels (1.A.1 energy industries; 1.A.2 manufacturing industries and construction; 1.A.3 transport; 1.A.4 other sectors; and 1.A.5 other) as well as *fugitive emissions from the extraction of fossil fuels* (1.B).

The combustion of solid, liquid and gaseous fuels for energy use has been identified as key sources in Australia's inventory.

The methodology for estimating emissions from fossil fuel combustion in the *stationary energy* sectors is consistent with the IPCC tier 2 approach. Tier 2 methods may be regarded as those dividing fuel consumption on the basis of sample or engineering knowledge between technology types which are sufficiently homogenous to permit the use of representative EFs. Emissions for the *transport* sector have been estimated with a mix of tier 1, tier 2, and tier 3 approaches.

The Department of Industry, Science, Energy and Resources compiled the *Australian Energy Statistics* (AES DISER 2021) which estimates Australian energy consumption by fuel and economic sector for the purpose of meeting Australia's reporting commitments to the International Energy Agency. National Greenhouse and Energy Reporting System (NGER) data has been adopted as the main energy consumption data source for the AES. Previously, the construction of historical energy statistics were based on the voluntary *Fuel and Electricity Survey* (FES). With the introduction of the NGER system, survey year 2008–09 became the final year that the FES was conducted. For survey year 2009–10 and onwards, NGER data has been used as the primary source of energy consumption data.

The AES provides a comprehensive and detailed ‘bottom-up’ quantification of energy use in Australia. To ensure internal consistency and completeness, the data are reconciled with ‘top-down’ statistics on the supply and use of all major fuels in Australia collected from the suppliers of those fuels, i.e. the coal, oil, gas and electricity industries.

3.2.1 CO₂ emissions and emission factors

In general, the estimate of emissions of CO₂ used for each fuel, *k*, in each economic sector, *h*, is estimated by:

$$E_{hk} = (F_{hk} \cdot EF_{hk} \cdot P_k / 100) - S_{hk} \cdot 44/12 \quad (3.1)$$

Where E_{hk} is the amount of CO₂ emitted from fuel *k* in economic sector *h* (in Gg)
 F_{hk} = the amount of fuel *k* combusted in sector *h* (in PJ)
 EF_{hk} = the CO₂ Emission factor (EF) (in Gg CO₂/PJ) for fuel *k*
 P_k = the oxidation factor (in per cent) of fuel *k*
 S_{hk} = the amount of carbon sourced from fuel *k* which is stored in sector *h* (in Gg)

Emission factors (EF) for CO₂ depend only on the chemical composition of the fossil fuel concerned under IPCC methods. For fuels having well defined and/or stable chemical composition, CO₂ EFs can be specified with considerable accuracy. This is particularly the case for natural gas and for petroleum products, with the exception of fuel oil, which may vary considerably in composition, and to a lesser degree for coals, which can vary in their composition of both combustible components (carbon, volatiles) and non-combustible components (ash, moisture).

Solid fuels

Coal

Approximately 90 per cent of all coal consumed in Australia is used by the electricity generation industry. Under NGER all electricity generators who consume coal as their primary fuel must sample and analyse their coal and report their facility specific CO₂ EF. The reported EFs are illustrated in Figure 3.14. After the electricity industry, the largest user of coal in Australia is the steel industry. The steel industry has provided a representative CO₂ EF of 91.8 Gg/PJ for black coal used in iron/steel/coke production (L. Leung, BHP 2001, pers. comm.). This figure has been further verified by industry data obtained from NGER as being representative. For black coal used in other industries, a representative CO₂ EF of 90.0 Gg/PJ has been derived from NGER data. All EFs are reported in Table 3.2.

A brown coal CO₂ EF of 93.5 Gg/PJ is applied to combustion other than electricity generation. The EF has been derived from facility data obtained from brown coal electricity generators reporting under NGER. The CO₂ EF of 95.0 Gg/PJ for brown coal briquette has also been derived from NGER data.

In the case of coal used for non-electricity generation, the coal CO₂ EFs are statistically tested each year against the mean of the population of newly measured EF's to determine whether there is any significant difference to the mean of the population of new measurements. This test ensures that the EF applied to coal consumers in non-electricity sectors is consistent with the population of measurements undertaken annually under NGER.

Coke

The CO₂ EF for coke is derived from a carbon balance conducted on the coke oven subsector. Carbon input into coke ovens is estimated and balanced against carbon contained in the fuel and product outputs from coke ovens. The carbon content of coke is determined as the carbon content required to achieve a carbon balance for the overall coke oven process. The resulting coke EF varies slightly from year to year depending on the balance of inputs and outputs, in a range between 103.8 and 109.4 Gg/PJ which is comparable to the IPCC default factor (Table 3.A.22). The underlying data used to estimate the coke EF is confidential due to the sector being characterised by a limited number of producers.

Coal By-Products

Coal by-product fuels are defined as coke oven gas, coal tar and liquefied aromatic hydrocarbons. They are produced largely as a by-product of coke oven processes, however liquefied aromatic hydrocarbons can also be produced from petroleum refining. An EF of 37 Gg/PJ has been assigned to coke oven gas following advice from the steel industry (Deslandes and Kingston 1997). The steel industry has also advised a representative EF for coal tar of 81.8 Gg/PJ. Liquefied aromatic hydrocarbons consist of compounds such as benzenes, toluene and xylene. Because of their similarities with naphtha and solvents, the same EF of 69.7 Gg/PJ was assigned to these products.

Liquid fuels

Refined Petroleum Products

Australian oil tends to be of the light crude variety and the petroleum products generated by Australian refineries reflect the characteristics of these supplies. The country-specific EFs for marketable petroleum products for this inventory are taken from GHD Australia (GHD 2006a), which reports the results of a review of Australian petroleum products. EFs are listed in Table 3.2. The EFs for petroleum fuels were further validated as being representative in a more recent review of Australia's liquid fuels characteristics conducted by Orbital Australia (Orbital 2011a). The Orbital review also confirmed the representativeness of the EF for fuel oil which was obtained from large industrial users of fuel oil (J. Le Cornu, pers. comm. 1996, J. Bawdin, pers. comm. 1996).

Other Petroleum Products

In the AES sectors, Basic Chemicals (ANZSIC Subdivisions 17–19), Oil and Gas Mining (ANZSIC Subdivision 07) and Basic Non-Ferrous Metals (ANZSIC Group 213–14) (after excluding petroleum coke from the latter sector), petroleum products not elsewhere classified (nec) consists largely of naphtha. The EF for naphtha of 69.8 Gg CO₂/PJ, (IPCC 2006), was therefore used in these sectors. For all other AES sectors in which petroleum products nec appears as a fuel type, an EF of 69.8 Gg CO₂/PJ is used based on IPCC 2006 default for Refinery Feedstocks and Other Petroleum Products.

Petroleum refining consumes refinery gas/liquids and refinery coke in the process of converting raw crude oil to refined products. EFs of 54.7 Gg CO₂/PJ (refinery gas and liquids) and 92.6 Gg CO₂/PJ (refinery coke) have been adopted from the 2006 *Guidelines* (IPCC 2006). Recycled tyres are combusted for energy within Cement, Lime, Plaster and Concrete (ANZSIC Group 203). The current EF of 81.6 Gg CO₂/PJ was sourced from the US Energy Information Administration (GHD 2006b).

Solvents and Bitumen

Australian information on CO₂ EFs for these products is not available. The factor for solvents (69.7 Gg/PJ) and bitumen (80.7 Gg/PJ) are based on the IPCC *Guidelines* (2006).

Gaseous fuels

Natural Gas

A national EF has been estimated for natural gas using data on the composition of natural gas in each pipeline system, as published by the Australian Gas Association (various years), weighted by the volumes of gas consumed from each pipeline system (see Table 3.2).

The CO₂ EF for natural gas varies slightly between States, depending on the composition of the gas supplied to energy users in the State, which in turn depends on the characteristics of natural gas in the fields from which supply is sourced. In these circumstances, use of a single national weighted average EF for all natural gas will not introduce errors at the level of aggregate national energy sector emissions. All emission estimates for natural gas are therefore based on national consumption data and national EFs, except for gas used for electricity generation. Under NGER all electricity generators that use gaseous fuels as their primary fuel are required to sample and analyse their natural gas or coal seam methane and report their facility specific EF. The reported EFs are illustrated in Figure 3.10. For small electricity generators who do not meet the reporting thresholds of NGER, the national CO₂ EF for natural gas is used.

An additional adjustment is made for natural gas activity data reported in the AES as used by the chemical industry because this includes both natural gas and the separate ethane supply that is used as feedstock. The ethane CO₂ EF used for the inventory was derived based on data within the *ASHRAE Handbook Fundamentals* (2001) and is 56.5 Gg CO₂/PJ. Ethane is the main source of feedstock and fuel supply for the petrochemical industry in Victoria, which is the location for a large proportion of the Australian petrochemical industry.

Town Gas

Town gas is a minor source of emissions and is given the same EF as LPG. It is assumed that in the manufacture of town gas, both carbon content and energy content is reduced in the same proportion, meaning that the carbon EF is unchanged.

Biomass fuels

Emissions of CO₂ from biomass fuels are not included in the national inventory but are required to be reported as a Memo item. The CO₂ EFs for bagasse and wood/woodwaste combusted in commercial and residential sectors are listed in Table 3.2. A detailed explanation of residential wood heater EFs is provided in section 3.6. Factors for bagasse (95.0 Gg/PJ) and ethanol (67.3 Gg/PJ) are based on IPCC 2006.

Table 3.2 Emission factors for CO₂

Fuel Type	Fuel	CO ₂ emission factor (Gg CO ₂ /PJ)
Coal derived fuels	Coal used in public electricity generation ^(a)	85.6–95.9
	Coal used in steel industry ^(ka)	91.8

Oxidation Factors for CO₂

The oxidation factor is defined as the proportion of carbon contained in a fuel which is oxidised to CO₂. Oxidation factors for fuels used in stationary energy are set at 1 with the exception of the special cases outlined below. An oxidation factor of 1 is consistent with the IPCC 2006 assumption of complete oxidation of carbon contained in fuel.

The IPCC 2006 Guidelines also recommend that where the fraction of non-oxidised carbon is known, ie in facility specific EFs or higher tier methods, then it is good practice to apply those oxidation factors. Data is available for Australia to adopt this approach for stationary energy EFs in the following circumstances:

1.A.1.a Electricity generation – coal fuels: – electricity generators are required to report facility-specific CO₂ EFs for primary fuels using sampling and analysis of their fuel inputs under the NGER system. Coal generators may sample and analyse their carbon in fly ash and furnace ash to determine a facility-specific oxidation factor which is incorporated into their reported emission factor. A detailed discussion on CO₂ EFs used in electricity generation is found at section 1.2.1.

1.A.4.b Residential – Biomass Combustion: – the CO₂ and non-CO₂ EFs for residential wood combustion are calculated using a detailed tier 2/3 model based on a large database of emission data and equipment types. The model accounts for all carbon in the fuel as combustion emissions or solid products of incomplete combustion in the form of ash and particulates. A detailed description of the residential biomass combustion method is found at section 3.6.2.

3.2.2 Non-CO₂ emissions

In addition to emissions of CO₂, the combustion of fuel in stationary source results in the emission of CH₄, N₂O, NO_x, CO, and NMVOCs. Of these, CH₄ and N₂O account for around 1 per cent of emissions, on a CO₂-e basis, in this sector. The magnitude of these emissions is dependent on a large number of factors, including fuel type, equipment design, and emission control technology. It is, therefore, inherently more complex and more uncertain than estimates of CO₂ emissions.

For non-CO₂ gases, emissions are estimated by:

$$E_{hkl} = F_{hk} \cdot E_{fhkl} \quad (3.2)$$

Where E_{hkl} = amount greenhouse gas l emitted from combustion of fuel type k, in economic sector h (in Gg)

F_{hk} = amount of fuel type k combusted in sector h (in PJ)

E_{fhkl} = technology weighted EF (in Gg/PJ) for greenhouse gas l, from fuel type k in sector h

The characteristics of the capital stock are an important determinant of the non-CO₂ emissions generated by the combustion of fossil fuels. Consequently, EFs for non-CO₂ are capital and technology-specific and require capital specific information to be collected, including equipment type, technology, and, in some cases, the age of capital.

The non-CO₂ factors are updated according to the IPCC 2006 and US EPA 2005b default values for uncontrolled emissions from various source categories, corrected for control technologies in use in Australia. In Australia, emissions from stationary fuel combustion source are controlled to varying degrees. The EFs for non-CO₂ greenhouse gases for each sector are summarised in Table 3.A.1. These derived EFs use weightings calculated according to the equipment type shares to reflect the mix of equipment types, including both stationary and mobile equipment, in use for those sectors. In the absence of evidence to differentiate gas variations in measured gas concentrations between boilers, differences cannot be attributed to differences in boiler type – e.g. tangentially-fired, boiler size, boiler load, or combustion modifications – e.g. low NO_x burners, it is assumed that the gas EFs are dependent on fuel type only.

For certain fuel types, due to absence and unavailability of data, industrial default emission factors for stationary combustion are applied to all non-CO₂ gases according to the IPCC 2006 guidelines and US EPA 2005b.

For the other economic sectors not covered by the above analysis, fuel use by equipment type and EFs for equipment types were estimated with a range of assumptions. For ANZSIC class Division A (Agriculture, Forestry, Fishing), it was assumed that all diesel is used in mobile equipment. It is assumed that the small quantities of other fossil fuels consumed in Division A are used in the agricultural industry, in miscellaneous small combustion equipment. For Division E (Construction), mobile equipment EFs are used. For Other Transport Services and Storage, 50–53, it was assumed that consumption of gaseous fuels occurs in gas turbines (used to power compressors in gas transmission and distribution systems) and all consumption of liquid fuels occurs in mobile equipment.

In ANZSIC subdivision 26, Electricity generation, data is available on the relevant equipment data for each power station.

3.2.3 SO₂ emissions

Data on default emission factors was obtained from the following sources:

- Petroleum products: Australian Institute of Petroleum and the National Pollutant Inventory;
- Natural gas and LPG: Australian Gas Association;
- Coal: the former Australian Government Department of Primary Industries and Energy.

Data for SO₂ emissions are available directly from reporting by facilities under the National Pollutant Inventory.

Table 3.3 SO₂ emission factors

Fuel	SO ₂ emission factors (Gg SO ₂ /PJ)
Black coal	0.37
Brown coal	0.15
LPG	0.002
Aviation gasoline	0.008
Kerosene	0.057
Heating oil	0.057
ADO	0.057
IDF	0.057
Fuel oil	1.282
Natural gas	0.002

Source: Australian Institute for Petroleum (pers. comm. 1996), National Pollutant Inventory (petroleum refining, DE 1998–2012), Department of Primary Industries and Energy (pers. comm. 1998) (for default coal values) and Annual Gas Industry Statistics (AGA 1988–1994).

3.2.4 Activity data

The Australian Energy Statistics (AES, DISER 2021) of energy use by economic sector and fuel has been compiled since the 1970s. The Department of Industry, Science, Energy and Resources compiled the 2020 Australian Energy Statistics.

The statistics provide a comprehensive and detailed 'bottom-up' quantification of energy use in Australia. They are reconciled with 'top-down' statistics of all major fuels in Australia, collected from the suppliers of those fuels, i.e. the coal, oil, gas and electricity industries. These statistics have been historically compiled from an annual fuel and electricity survey supplemented by a variety of other sources of information.

The Australian Energy Statistics utilises data collected under NGER as the primary source of energy consumption data. NGER reporting is compulsory for facilities over specified energy and emissions thresholds and provides greater coverage than was available from the previous voluntary Fuel and Electricity Survey.

The Department has supplemented NGER data with information from other Australian Government agencies, state-based agencies and industry associations. As in the past, in sectors with low or no NGER coverage (commercial and services, agriculture and residential), energy consumption was estimated using the energy balance process and other estimation techniques. The Australian Energy Statistics provides a comprehensive and detailed 'bottom-up' quantification of energy use in Australia. To ensure internal consistency and completeness, the data is reconciled with 'top-down' statistics on the supply and use of all major fuels in Australia collected from the suppliers of those fuels.

The data is presented in common energy units (PJ) on an individual State basis. Historically, the Australian Energy Statistics collected statistics of energy use by equipment (technology) type. These have been used to compile the technology weighted sectoral EFs for non-CO₂ greenhouse gases.

Several re-allocations to the Australian Energy Statistics are required in order to:

- break down energy consumption into sub-sectors where this is required to match Common Reporting Format (CRF) table categories;
- identify and allow for stored carbon;
- separate coke production from other parts of the iron and steel industry;
- eliminate double counting of gas leakage from the gas distribution system; and
- allocate fuel use to the industrial process sector for the estimation of emissions from the use of fuels as reductants.

The Australian Energy Statistics undertakes reconciliation at the level of the supply and use of energy in the economy at the level of energy units. The Australian Energy Statistics analysis ensures that all energy entering the economy is accounted for by end-uses.

Revisions are made to the AES to update the data in previous years of the series. These revisions are made to ensure that the AES presents an accurate picture of Australian energy production and use, including in historical periods. Often a revision will reflect changes in source data, such as the NGER or Australian Petroleum Statistics. The AES can also be revised to correct errors or to account for changes in estimation techniques. Additional information regarding revisions is available in the Guide to the Australian Energy Statistics, available at the following web link: https://www.energy.gov.au/sites/default/files/Guide%20to%20the%20Australian%20Energy%20Statistics%202021_0.pdf.

These recalculations are incorporated into the inventory as they become available.

Activity data for the time series 1990 to 2020, reported by category level and fuel type, is available on the AGEIS website: <https://ageis.climatechange.gov.au/>

3.2.5 Feedstock and non-energy fuel use

Activity data and emissions associated with the non-energy use of fuels are not reported within the fuel combustion subsector. In accordance with the 2006 IPCC *Guidelines*, they are reported under the *industrial processes and product use* sector and *fugitive emissions from fuels* sub-sector as follows:

Reported in *industrial processes and product use*:

- Coke and natural gas where used as a reductant in the integrated coke/iron and steel production – reported in 2.C.1 Iron and Steel Production;
- Pulverised black coal where used as a reductant in the integrated coke/iron and steel production – reported in Iron and Steel Production;
- Black coal where used as a reductant in synthetic rutile production – reported in 2.B.6 Chemical Industry – Titanium Dioxide Production;
- Black coal, coke, petroleum coke and fuel oil where used as a reductant in base metal production – reported in Ferroalloys Production and 2.C.7 Other;
- Petroleum coke where used as a reductant in titanium dioxide production – reported in 2.B.6 Chemical Industry – Titanium Dioxide Production;
- Petroleum coke, coal tar and coke used for anodes in aluminium production – reported in 2.C.3 Aluminium Production;
- Natural gas used in Ammonia production – reported in 2.B.1 Ammonia Production;
- Coke where used as a reductant in soda ash production – reported with other emissions from soda ash production in 2.B.7 Soda Ash Production.; and
- Lubricants and grease consumption where used for non-energy purposes – reported in 2.D.I.

Reported in fugitive emissions from fuels

- Oil refinery flaring – reported in 1.B.2.a. Oil Refining/Storage; and
- Natural gas leakage – reported in 1.B.2.b Natural Gas Distribution.

3.2.6 QA/QC

The carbon balance

A carbon balance for all years was undertaken in terms of the supply and use of carbon from fuels in the economy. All carbon entering the economy is accounted for either as emissions from fuel combustion, emissions from the use of fossil fuels as reductants, non-energy uses, use of biomass source of energy and international bunkers. While the predominant outcome of carbon entering the economy is emissions, a small portion of the total is stored in carbon-containing products or non-oxidised as ash.

Tables detailing the results of the carbon balance can be found in Annex 6.

Comparison with international data

IEFs for all major fuels are tested for differences against the mean of the population of all other available Annex I data. For each major fuel, the t-tests conducted show that the implied CO₂ EFs for Australian fuels are not significantly different to the mean of the implied EFs for the Annex I population.

The Australian Energy Statistics is the common source of energy data for the preparation of the national inventory, as well as the basis for Australia's report to the International Energy Agency (IEA). Some differences occur from year to year between the activity data in the inventory CRF tables, and the data published by the IEA.

A project has previously been undertaken to reconcile the data provided to the IEA with the published Australian Energy Statistics data used in the inventory. The Department found that the data reported to the IEA by the DIIS, the Australian Government department previously responsible for the *Australian Energy Statistics*, is consistent with the data published in the *Australian Energy Statistics* (in petajoules units).

The investigation found the following reasons for differences between data reported by Australia in the CRF tables and data published by the IEA:

- The energy conversion used by the IEA is a significant cause of the differences, with the data provided to the IEA being processed by methods outside of the control of Australia (including the use of default energy content values as compared to facility specific NGER data); and
- Coal production data reported in the CRF tables are significantly higher (around 13–25 per cent) than those reported to the IEA. The reason for this difference is that the coal production reported to the IEA only comprises black coal production and does not include brown (lignite) coal production. The IEA data does correspond with coal production reported in Australia's CRF table when brown coal production is included.

During July 2014 the IEA conducted a Statistics Mission to Australia. Officers of the Department responsible for compiling the National Inventory Report had the opportunity to raise with the IEA the issue of differences between data reported by Australia in the CRF tables and data published by the IEA. The IEA observed that at the higher level, the CRF fuel consumption was generally in good agreement with the IEA. A better understanding as to why differences exist between the IEA/CRF tables for petroleum fuels was established; Australia submits petroleum data on the 5th of each month to the IEA, whereas the CRF tables are based on the AES which represent Australia's financial year (i.e. 1 July 2019 to 30 June 2020). Therefore differences will exist due to accounting period inconsistencies and revisions to data published annually in the AES.

In addition, recent investigations has revealed that only the most recent year of data is appended and published by the IEA. This results in time series discrepancies when compared to later AES publications.

3.3 Source Category 1.A.1 Energy industries

3.3.1 Source category description

This category includes emissions from fuel combustion within electricity generation, petroleum refining and other energy manufacturing industries such as coke ovens, briquette production, coal mining, oil and gas extraction, and natural gas production and distribution. The Australian Energy Statistics reports energy consumption for economic sectors defined using the Australia New Zealand Standard Industrial Classification (ANZSIC) developed by Australia's national statistical agency, the Australian Bureau of Statistics. The mapping of data to IPCC classifications from the ANZSIC codes is complete and reported in Table 3.4.

Table 3.4 Relationship between IPCC source categories and ANZSIC sectors: Energy Industries

IPCC Source Category	ANZSIC Subdivision		
	Division	Subdivision	Description
1. A.1 Energy Industries			
a Electricity and heat production ^(a)	D Electricity, Gas and Waste Services	26	Electricity supply
b Petroleum refining	C Manufacturing	1701	Petroleum refining
c Solid fuel transformation and other energy industries	B Mining and C Manufacturing		Coal mining (incl. briquette production)
	B Mining		Oil and gas extraction (incl. gas processing and LNG production)
	C Manufacturing	21	Coke ovens associated with Basic iron and steel manufacturing
	D Electricity, Gas and Waste Services	27	Gas supply

Note: (a) There is no public generation of distributed heat in Australia.

3.3.2 Methodology

In summary, emissions for the *energy industries* category are estimated using tier 2 approaches and country specific factors (Table 3.5).

Table 3.5 Summary of methods and emission factors: Energy Industries

Categories	CO ₂		CH ₄		N ₂ O	
	Method applied	Emission factor	Method applied	Emission factor	Method applied	Emission factor
1A1a Public electricity	T2	PS, CS	T2	CS	T2	CS
1A1b Petroleum refining	T2	CS, PS	T2	CS	T2	CS
1A1c Manufacture of Solid Fuels	T2	CS	T2	CS	T2	CS

Notes: T1 = tier 1, T2 = tier 2, T3 = tier 3, CS= Country-specific, D= IPCC default, PS = Plant Specific.

Electricity Generation (ANZSIC Subdivision 26) (I.A.I.a)

Electricity generation includes power for supply to the grid (whether the power stations are owned by public or private corporations). Public heat production does not occur in Australia.

Choice of emission factors

A tier 2 approach is used for the key category of electricity generation in which EFs for fuels such as coal vary from source to source and over time. The fundamental reporting unit in this sector is the individual power station.

Data is collected from power stations through the NGER system. Under the NGER, facilities over certain thresholds are required to submit annual data on fuel consumption, fuel energy content, fuel EFs (incorporating oxidation factors), emission estimates and the amount of electricity generated and sent out to the Clean Energy Regulator. Power stations must sample and analyse their primary solid and gaseous fuels in accordance with the requirements and standards listed in the *National Greenhouse and Energy Reporting (Measurement) Determination 1998* (Cwth). The adoption of these methods and standards ensures accuracy and comparability in the facility specific information reported. This data provides facility specific energy content and EFs for the solid and gaseous fuels consumed in each power station.

Prior to the establishment of NGER, methods for estimation were provided by the Generator Efficiency Standards program – as detailed in the *Generator Efficiency Standards Technical Guidelines* (AGO 2006a). The adoption of consistent methods in the NGER and the Generator Efficiency Standards program ensured time series consistency in the emission estimates in the national inventory.

Country-specific EFs are utilised for minor (mainly liquid) fuels.

Activity data

NGER data is received from all large and medium sized power stations in Australia. This data is currently available for around 140 fossil fuel based power stations in Australia. The energy use of small power stations that do not meet the NGERS reporting thresholds, are estimated as the difference between the total of reported values under NGERS and Australian Energy Statistics for ANZSIC subdivision 26. This approach has been adopted throughout the time series. Therefore the improved coverage of power stations under NGERS does not alter the method for estimating total fuel consumption in this sector. The coverage of individual coal power station NGER data is comprehensive and has displaced the necessity to use AES data to inform coal activity data.

Research conducted by BREE on regional and remote electricity generation in Australia (BREE 2013b) was used in 2013 to validate or update the fuel consumption totals estimated in the *Australian Energy Statistics*. This research surveyed off-grid electricity generated and consumed outside of the major electricity grids of Australia, including the smaller grid systems of the Pilbara, Darwin to Katherine and the Mt Isa areas. The fuels covered in the survey are natural gas, diesel oil and fuel oil.

Under the NGER system, oxidation factors and the emission factors are linked in that coal power station operators report CO₂ EFs including the effects of oxidation based on analysis of ash contents and in accordance with the *NGER Measurement Determination 2008* (Cwlth). In such cases applying an additional oxidation factor would double-count the effect of incomplete combustion, so an oxidation factor of 100 per cent is used. The *NGER Measurement Determination 2008* requires emission factors reported by generators to use a default oxidation factor of 100 per cent unless measurements are undertaken to support an alternative value. Figure 3.10 shows the distribution of emission factors reported by electricity generators for major fuel types.

CH₄ and N₂O emissions from landfill gas captured for combustion for electricity generation are reported in this subsector and CO₂ emissions are reported as a memo item.

Figure 3.10 Emission factors for CO₂ in electricity generation, Australia, 2020

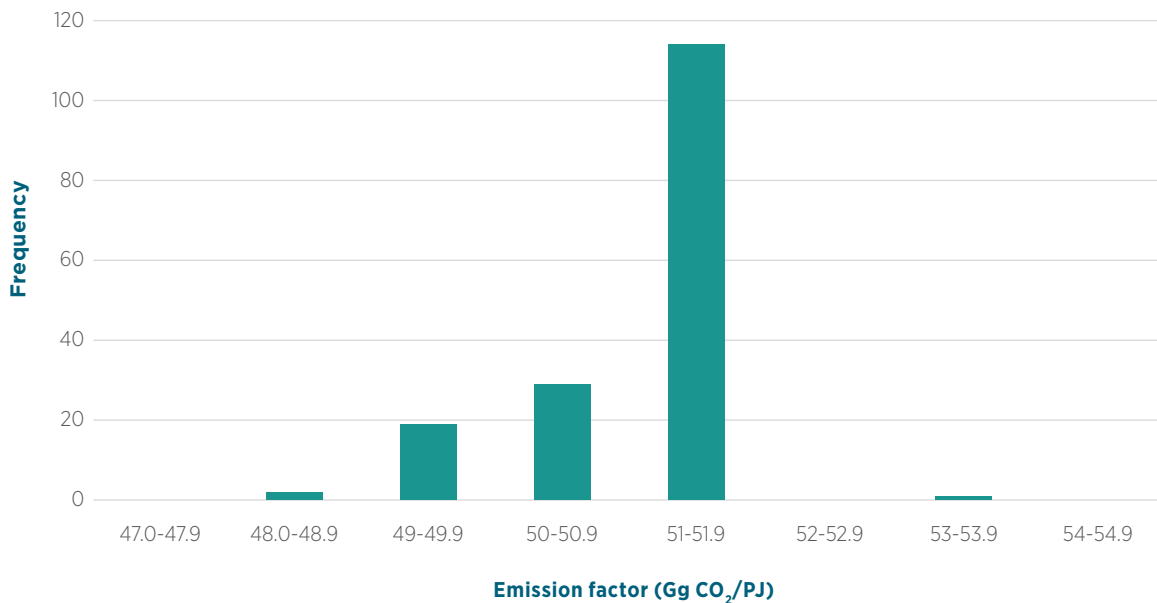

(a) Black Coal power stations

(b) Brown Coal power stations

(c) Natural gas and waste gas power stations

Source: NGER.

Notes: Values incorporate the effect of partial oxidation of fuels.

Petroleum refining (ANZSIC Class 1701) (I.A.I.b)

The main fuels used by petroleum refineries are refinery gas/liquids and natural gas along with some minor use of other liquids fuels. The combustion of refinery coke is also included under Petroleum Refining I.A.I.b. The *Australian Energy Statistics* reports refinery feedstock, i.e. essentially crude oil, as the major input, together with other undefined petroleum products. The various market petroleum products are shown as energy outputs. The total energy content of the products produced by the sector is less than the energy content of the petroleum input, with the difference being energy consumed by the refining processes (distillation, cracking etc.). The fuel from which this energy is derived is obtained from the crude oil input and is referred to as refinery fuel.

Choice of emission factor

NGER data made available facility-specific EFs for the fuels; refinery gas and liquids, refinery coke and natural gas from several of the petroleum refineries. A decision to utilise these factors for the relevant refineries while maintaining the default factors for the remainder, was made in consultation with the decision tree in section 1.4.1. In doing so, it was recognised that refinery EFs for these fuel types are strongly linked with the specific technology types and process configurations inherent in individual refineries.

Activity data

The refinery fuel balance contained in the AES is analysed using a model that examines the expected refinery plant efficiency in the conversion of crude oil to final products, taking into account factors such as the change to low sulphur diesel. The model is used to derive refinery fuel consumption for the years 2000 to 2008. This is in response to QC analysis demonstrating that the AES petroleum refining data does not provide representative activity data using an input/output balance method for that period.

Detailed fuel consumption data was made available via the NGER for all Australian oil refineries from 2009 to 2018. In particular, NGER data provides details on the refinery fuel use, enabling a split between the combustion of refinery gas/liquids and the burning of refinery coke to restore the activity of the catalyst during the refining process. Given that this component of petroleum refining emissions has previously been included within total refinery fuel combustion, it was decided to continue with this practice for this submission in order to maintain time series consistency. This remains consistent with practice followed by most other countries and the 2006 IPCC *Guidelines* are unclear as to where emissions from this source should be reported. For transparency purposes, these emissions from refinery coke have also been noted in the Fugitives – petroleum refining section of this Report. Refinery flaring is accounted for in the *Fugitive Fuel Emissions* sector.

Implied Emission Factor

Due to the direct reporting under NGER of plant specific data, the total gaseous fuel IEF for petroleum refining fluctuates through the time series. Other gaseous fuels are reported under the other fossil fuel category to allow a comparable natural gas IEF to be estimated. Being reliant on NGER reporting, this IEF may still fluctuate through time depending on plant closures and reported fuel categories.

Manufacture of Solid Fuels and Other Energy industries 1-A-1.c

The manufacturing of solid fuels and other energy industries sector, 1.A.1c, comprises six ANZSIC sectors:

- Coke Oven Operation (ANZSIC Subdivision 21);
- Briquetting (ANZSIC Subdivision 17);
- Coal Mining (ANZSIC Division B);
- Oil and Gas Extraction (ANZSIC Division B);
- Other Transport Services and Storage, assumed to be gas pipeline transport (ANZSIC Subdivision 50–53); and
- Gas Supply (ANZSIC Subdivision 27).

Estimated emissions are derived from equations 3.1 and 3.2 and the EFs reported in Tables 3.2 and 3.3 and Table 3.A.1.

The *Coke Oven Operation* (ANZSIC Subdivision 21) sub-sector is effectively a subsidiary activity of the iron and steel industry but is classified by the IPCC as an energy transformation industry and hence is reported separately. This sub-sector is both a consumer of black coal and coal by-products and a producer of coke and coal by-products. Consequently, fuel combustion is calculated by deducting derived fuels produced by the sector from energy inputs. Additional information is provided to improve the transparency of activity data for the black coal/coke oven gas fuel mix consumed in 1.A.1.c Manufacture of Solid Fuels and Other Energy Industries sector. The percentage of black coal/coke oven gas fuel mix is shown in Table 3.6.

Table 3.6 Percentage of black coal and coke oven gas fuel mix in 1.A.1.c

Years	per cent of coal	per cent of coke oven gas
1990	86	14
2000	72	28
2005	66	34
2006	81	19
2007	82	18
2008	82	18
2009	79	21
2010	82	18
2011	82	18
2012	81	19
2013	82	18
2014	81	19
2015	78	22
2016	78	22
2017	76	24
2018	59	41
2019	59	41
2020	59	41

The *Gas Production and Distribution (ANZSIC Subdivision 27)* sector is also one of the energy transformation industries, manufacturing town gas up until 2012 from both natural gas and LPG. Fuel consumption consists of:

- natural gas and LPG used to make town gas; and
- other gas (including both natural gas and town gas) used by the industry for its own purposes.

The quantity of town gas produced is shown as an energy output of the sector in the *Australian Energy Statistics*.

It was assumed that all LPG is converted to town gas, and none is combusted in the conversion process. LPG consumption was therefore offset in full against an equal quantity (in terms of energy content) of town gas produced. The remaining town gas production was subtracted from total natural gas consumption.

Oil and Gas Extraction (1.A.1.c.ii)

Methane emission factors for four-stroke rich burn/lean burn engines were taken from EPA AP-42 and weighted in the proportions observed by Zimmerle et al 2020 in the US industry to derive a single methane emission factor for reciprocating engines of 404.61 t CH₄/PJ for use in the Australian inventory.

Additional information regarding the fugitive emissions associated with gathering and boosting stations is available in *Natural gas (1.B.2.b)*.

3.3.3 Uncertainties and Time Series Consistency

The tier 1 uncertainty analysis in Annex 2 provides estimates of uncertainty according to IPCC source category and gas.

Time series variability of GHG IEFs are also likely to be influenced by changes in fuel mix within categories, and changes of facility specific fuel EFs. Notable examples of where such variations occur in 1.A.1 *energy industries* are set out below:

- 1.A.1.c *manufacture of solid fuels and other energy industries* – CO₂ from solid fuels: The IEF declines by 10 per cent between 1990 and 2001. This can be explained by the relative rise of coal by-products – coke oven gas as a fuel (with a relatively low EF of 37 Gg/PJ) at the expense of black coal; and
- 1.A.1.a *public electricity* – CO₂ from biomass: Biomass combustion for electricity consists of a growing proportion of biogas from landfill. Biogas has a relatively low CO₂ emission factor compared to other biomass fuel, hence Australia's CO₂ biomass IEF is relatively low.
- 1.A.1.a *public electricity* – CO₂ from liquid fuels: Variations occur in the IEF over the time series due to changes in the proportions of Fuel Oil and Diesel Oil in the liquid fuel mix. These fuels have consumption variability year on year as they are generally used for unscheduled and off-grid electricity generation.
- 1.A.1.b *petroleum refining* – CO₂ from liquid fuels: Variations in the IEF of around 2 per cent are evident since 2008. The estimation of CO₂ for the petroleum refining sector utilises facility-specific emission factors obtained from the NGER system. The CO₂ IEF will tend to vary depending on the liquid fuel mix used and the refinery processes undertaken in the year. Australia has a limited number of refineries (5 in 2019). Therefore changes in fuel mix and qualities in those refineries will tend to result in minor variations in the overall liquid IEF.

3.3.4 Source specific QA/QC

This source category is covered by the general QA/QC measures of the greenhouse gas inventory discussed in Chapter 1. Results for the reference approach for the *energy* sector, reported in Annex 4, and the carbon reconciliation reported in Annex 6, provide quality control checks for this sector.

Fuel and generation data for 1.A.1.a *public electricity* are compiled by the Department from NGER data and from Australian Energy Statistics energy data. Activity and emission input data is fully reconciled against the emission outputs to ensure the accurate reporting in this sector.

Fuel and generation data are also checked and reconciled against the alternative data source of the Energy Supply Association of Australia (ESAA) and the Australian Energy Market Operator (AEMO). These comparisons confirm the consistency of the estimates to a high level of accuracy and show that all energy/carbon has been accounted for.

A top-down/bottom-up reconciliation and verification using supplementary data was undertaken for natural gas consumption in the inventory, as a means of verifying recalculations for natural gas with 1.A.1 – see section 3.2.6 QA/QC.

Emissions and activity data for coke ovens are estimated within an overarching carbon and energy balance that encompasses the Australian Iron and Steel production sector.

3.3.5 Recalculations since the 2019 Inventory

Recalculations to 1.A.1 energy industries are detailed at the sub-category level in Table 3.7.

Revisions in the Australian Energy Statistics are reflected in a recalculation in 1.A.1.a. This recalculation is the result of approximately 0.4 PJ of diesel being added and 14 PJ of natural gas being removed.

A previous ERT recommendation has been actioned to allocate any known refinery gas used in petroleum refining to liquid fuels and if the amounts and type of other gaseous fossil fuels from NGRS reporting are not known with sufficient certainty, to allocate them to other fossil fuels in the CRF category 1.A.1.b and only report natural gas under gaseous fuels. This does not result in an emissions recalculation but is instead a reallocation between fuel types.

Table 3.7 1.A.1 Energy Industries: recalculation of total CO₂-e emissions, 1990–2019

3.3.6 Planned improvements

The Department will continue to look at applying revisions through to the earlier part of the time series in future Australian Energy Statistics releases and these revisions will be incorporated into future recalculations of the national inventory when available.

Further facility specific data from NGER will be incorporated into the activity data. This will reduce differences between the total of reported values under NGER and the Australian Energy Statistics for ANZSIC subdivision 20.

NGER data collection processes will be examined to explore the possibility of collecting facility specific data on technology types used for gas combustion on site at gas plants.

3.4 Source Category 1.A.2 Manufacturing Industries and Construction

3.4.1 Source category description

This source category includes emissions from fuel combustion in manufacturing, construction and non-energy mining. This includes both stationary and mobile equipment such as earth moving and mining equipment.

The Australian Energy Statistics report energy consumption for economic sectors defined using the Australia New Zealand Standard Industrial Classification (ANZSIC). The mapping of ANZSIC codes against IPCC classifications is complete and given in Table 3.8.

Table 3.8 Relationship between IPCC source categories and ANZSIC sectors: Manufacturing and Construction

IPCC Source Category	ANZSIC Subdivision/Group/Class			
	Division	Subdivision	Group/Class	Description
2. Manufacturing Industries and Construction				
A Iron and Steel	C Manufacturing	21	211-212	Iron and steel manufacturing (excl. Coke ovens)

G Construction	E Construction			Construction

3.4.2 Methodology

The emissions for *manufacturing industries and construction* are estimated using tier 2 approaches (Table 3.9). Emissions estimated from activity data are based on the energy consumption by industry sector and fuel type compiled by the DISER. CO₂ EFs are country-specific and direct industry advice on the use of CO₂ emissions factors has been adopted for the use of coal by-products within *I.A.2.C chemicals*, black coal within *I.A.2.a iron and steel*, and natural gas in general. Non-CO₂ EFs have been calculated using a sectoral equipment-weighted average approach and are reported in Table 3.A.2. More detail is provided for the metal and chemicals industries.

Table 3.9 Summary of methods and emission factors: Manufacturing and Construction

Category	CO ₂		CH ₄		N ₂ O	
	Method applied	Emission factor	Method applied	Emission factor	Method applied	Emission factor
1A2a Iron and Steel	T2	CS	T2	CS	T2	CS
1A2b Non-Ferrous Metals	T2	CS	T2	CS	T2	CS
1A2c Chemicals	T2	CS	T2	CS	T2	CS
1A2d Pulp, Paper and Print	T2	CS	T2	CS	T2	CS
1A2e Food Processing, Beverages and Tobacco	T2	CS	T2	CS	T2	CS
1A2f Non-metallic minerals	T2	CS	T2	CS	T2	CS
1A2g Other	T2	CS	T2	CS	T2	CS

Notes: T1 = tier 1, T2 = tier 2, T3 = tier 3, CS= Country-specific, D= IPCC default.

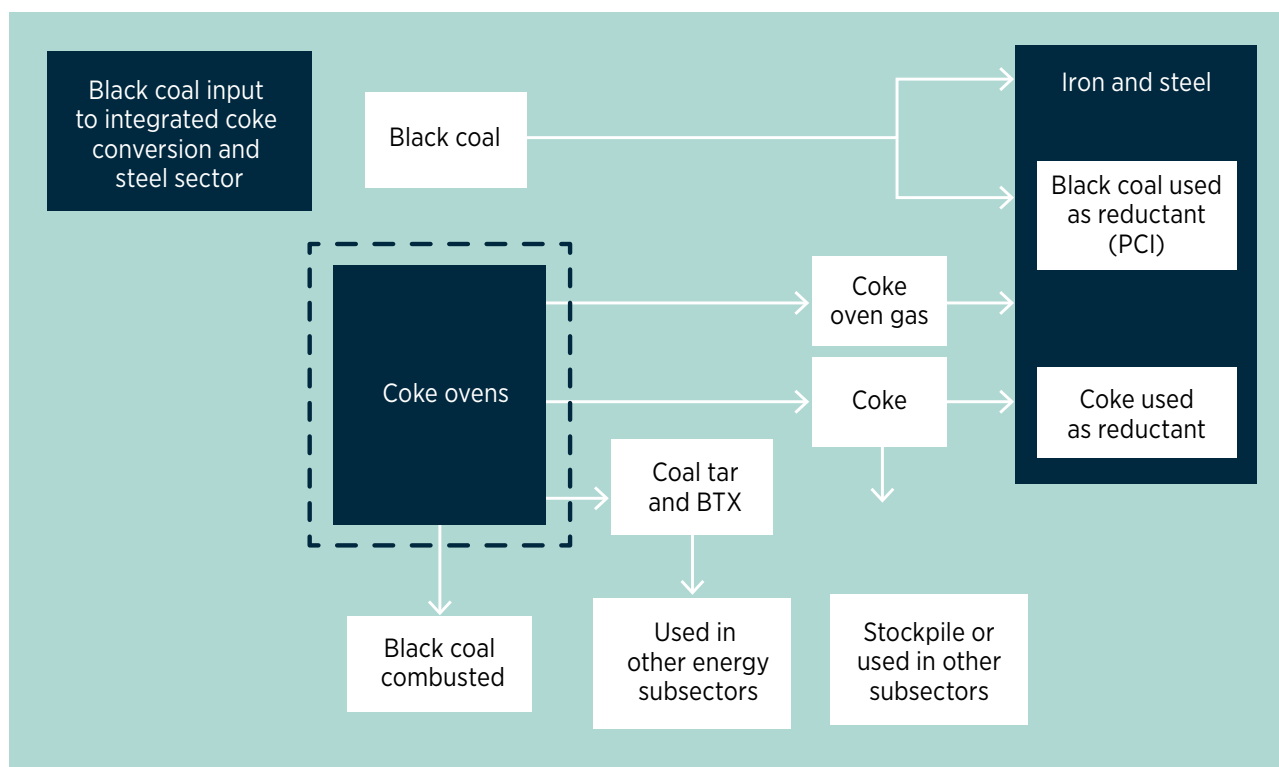

Iron and Steel (ANZSIC Subdivision 21) (1.A.2.a)

The methodology in the *iron and steel* sub-sector is somewhat more complex than many other sections of the inventory. This complexity arises from a number of factors:

- The operation of Coke Ovens is considered to be an energy transformation industry, and hence must be reported separately to the rest of the iron and steel emissions;
- The production of coke yields a variety of by-products, including coke oven gas, coal and tar;
- Liquefied aromatic hydrocarbons and naphthalene, each having quite different calorific values and EFs. Coke oven gas is used as fuel in coke ovens and adjacent steelworks, while the other products are in general not combusted, but are used as feedstock in the chemical industry;
- Overall, the Coke Ovens sector is a producer of coke, most of which is consumed in the Iron and Steel sector and some of which is exported to other sectors (and other countries);
- The operation of blast furnaces to produce pig iron also produces yet another coal by-product, blast furnace gas, which is a low calorific value fuel consisting mainly of CO (and atmospheric nitrogen), used elsewhere in the steelworks. For the purpose of calculating CO₂ emissions, the production and subsequent combustion of blast furnace gas is ignored, and it is assumed that all coal and coke used in the iron and steel industry undergoes complete oxidation to CO₂, apart from a small adjustment for carbon sequestered in steel;
- The use of coke, as well as natural gas in hot briquetted iron production is regarded primarily as a chemical process rather than fuel combustion under IPCC reporting *guidelines*. Consumption and emissions are therefore reported under the *industrial processes and product use* sector 2.C.3 rather than the *energy* sector;
- Pulverised black coal has been used as a reductant in the production of iron since 2003. Therefore the consumption and emissions are now reported under the *industrial processes and product use* sector in 2.C.1 *metal production* rather than the *energy* sector;
- Although Coke Ovens are in operation in the iron and steel industry, they are considered an energy transformation industry under the IPCC methodology. Therefore, Coke Ovens must be separated from the other parts of the iron and steel industry, so that it can be reported under IPCC category 1.A.1.c;
- The statistics show that production of both coke and coal by-products exceed consumption within the sectors, i.e. the iron and steel industry as a whole is a net producer of coke and coal by-products. Only the estimate of consumption is used to estimate emissions from the Iron and Steel sector. Some of the remaining production may appear elsewhere in the national inventory if it is consumed as fuel by other industries in Australia, in which case the emissions are allocated to the consuming industry; and
- Production consumed elsewhere includes some coke (though in most years the majority of surplus coke produced by the industry is exported from Australia), and surplus coal by-products, most of which are consumed by the Coal and Petroleum Products sector.

A schematic chart showing energy flows within the integrated coke oven/Iron and Steel subsectors is shown in Figure 3.11. Energy and carbon flows are balanced between input and outputs when compiling the inventory as part of the inventory quality controls – See QC control 3.B.1 (i) carbon and energy balances (NIR Volume 3, Table A6.2: Australia's National Carbon Balance and Figure A6.1.) A discrete carbon balance is undertaken around the coke ovens input/output, as defined by dashed lines in Figure 3.11, to determine the carbon content of coke produced as a balancing item. The coke emission factor determined from this balance is shown for all years in Table 3.A.21.

Figure 3.11 Coke Oven and Iron and Steel energy flow chart

Note: The dashed lines define the discrete carbon balance undertaken for the coke oven inputs/outputs to determine the carbon content of the coke produced.

Non-Ferrous Metals (ANZSIC Group 213–214) (1.A.2.b)

The consumption of petroleum products nec (meaning other, unspecified petroleum products 'not elsewhere classified') in this sector includes petroleum coke and coal tar used to make carbon anodes for aluminium production. CO₂ emitted from oxidation of carbon anodes in aluminium smelters is accounted in UNFCCC category 2.C.3. The quantity of petroleum coke and coal tar consumed in this sector, as advised by industry each year, is therefore subtracted from energy consumption of petroleum products nec and coal by-products, in order to eliminate double counting. It is assumed that the remaining energy consumption of Petroleum Products nec consists of naphtha. Some use of black coal in the production of synthetic rutile as well as black coal, coke, petroleum coke and fuel oil for base metal smelting occurs for reductant purposes. Therefore, these fuel quantities are also deducted from the *energy* sector fuel consumption and reported under the *industrial processes and product use* sector.

Chemicals (1.A.2.c)

This sub-sector spans the following ANZSIC classes:

- Other petroleum and coal product manufacturing (ANZSIC Class 1709); and
- Basic chemical and chemical, polymer and rubber (ANZSIC Subdivision 18–19).

The Chemicals sector is a major energy user. Most of the energy is used by the Petroleum Refining and Basic Chemical Manufacturing sub-categories. Energy use in these two sub-categories is separately reported at the national level.

Non-energy use of natural gas in the production of ammonia is regarded as an industrial process and is therefore reported under the *industrial processes and product use* sector rather than the *energy* sector, in order to prevent double counting. Likewise, the non-energy use of petroleum coke for titanium dioxide production and coke oven coke used in soda ash production are also reported within the *industrial processes and product use* sector.

The calculation of emissions in the Chemicals sector must identify and allow for carbon stored in products. Sequestration takes place in the Other petroleum and coal product manufacturing (ANZSIC Class 1709) and Basic chemical and chemical, polymer and rubber (ANZSIC Subdivision 18–19) sub-categories, where fossil fuels are used as feedstock. Data is also obtained directly from chemical companies in order to estimate the quantity of carbon sequestered in products from feedstocks, with emissions estimates adjusted accordingly.

Coal by-products constitute the largest fuel input into the Other petroleum and coal product manufacturing (ANZSIC Class 1709) sector. It is assumed that these consist of coal tar and liquefied aromatic hydrocarbons and that, in the absence of specific information about this industry sector in Australia, 75 per cent of this fuel is sequestered in long lived coal products, following the default assumption of the IPCC methodology.

The basic chemical and chemical, polymer and rubber (ANZSIC Subdivision 18–19) sub-category includes the major bulk chemical manufacturing enterprises producing fertilisers, other nitrogenous chemicals, polymer resins (plastics) and carbon black. The fossil fuel feedstocks used include natural gas (CH₄), ethane, propane, butane, propylene and naphtha. Ethane, propane and butane may be either 'naturally occurring', i.e. sourced directly from oil and gas fields, or derived from crude oil as by-products of refining. In Australia, all ethane is derived from naturally occurring source, while both naturally occurring and ex-refinery propane and butane are used. Propylene and naphtha are refinery products. The Australian Energy statistics include ethane within the reported total natural gas consumption, after appropriately adjusting for the different energy content of ethane. The Australian Energy Statistics also groups propane and butane together as LPG and group propylene and naphtha as petroleum products nec.

The important outputs of this sector can be classified into two components:

- synthetic resins (polymers); and
- nitrogenous fertilisers and other nitrogenous products.

A third component, carbon black manufacture, uses significant quantities of fossil fuel feedstock as a source of carbon, however relatively little is combusted. A fourth, methanol, has been manufactured in Australia since 1994.

Synthetic Resins

The balance between combustion and storage in products varies greatly between chemical plants, depending on the production processes involved and the configuration of the particular plant. Therefore the quantity of feedstock supplied to chemical plants is not a useful indication of the quantity of stored carbon. The only reliable guidance comes from the quantities of chemical products produced. The major products in which fossil carbon is sequestered include polyethylene, polypropylene, synthetic rubber and styrene. Other bulk plastics are made in Australia from imported monomers, e.g. PVC made from imported vinyl chloride monomer. These imported monomers contain large quantities of fossil carbon, but since this has not been derived from primary fossil fuels (crude oil, petroleum products and natural gas) produced in or imported to Australia, this carbon is not estimated.

The IPCC Methodology assumes that default fractions of specified fossil fuel products, e.g. ethane, naphtha, are sequestered. The national inventory utilises the actual production figures provided by the companies making the products concerned. The analysis is nevertheless relatively complex, because most products are derived from several different feedstocks. The carbon contents of the various feedstocks and basic chemical products used in estimating the carbon sequestration are reported in Table 3.10 and Table 3.11.

The quantities of feedstocks used in the Chemical sub-sector, and the associated amounts of carbon stored in products, are detailed in CRF table 1.A(d) – Feedstocks and non-energy use of Fuels. The majority of emissions of ethane and naphtha combusted as fuels are reported in the national inventory under *1.A.2c Chemicals*.

Carbon Black

Carbon black is produced in Australia by partial oxidation of petroleum feedstocks and used in a variety of long lived products, including tyres.

Table 3.10 Feedstock assumptions in basic chemicals

Feedstock	Carbon Faction	Calorific Value (GCV)
Ethane	0.80	(a)
Propylene	0.86	52.2
Naphtha (Benzene)	0.84	48.1
Gas Oil (ADO)	0.85	45.6
Carbon Black Feedstock	(a)	(a)

Table 3.11 Product assumptions in basic chemicals

Product	Carbon Faction
Polyethylene	0.86
Polypropylene	0.86
Butadiene Rubber / Styrene-Butadiene Rubber	0.86
Styrene	0.92
Carbon black	1.00

3.4.3 Uncertainties and time series consistency

The tier 1 uncertainty analysis in Annex 2 provides estimates of uncertainty according to IPCC source category and gas.

Time series variability of GHG IEFs are likely to be influenced by changes in fuel mix within categories. Notable examples of where such variations occur in Manufacturing Industries and Construction 1.A.2 are set out below.

1.A.2.a iron and steel: CO₂

Solid fuels

The use of coke in iron and steel is reported in industrial processes and product use sector in accordance with the 2006 IPCC Guidelines. Of the two remaining solid fuels: coal and coke oven gas, the coke oven gas has a relatively low CO₂ EF of 37 Gg/PJ compared to 91.8 Gg/PJ for coal. This tends to lower the overall CO₂ IEF for solid fuels.

Following the recommendation of the 2008 ERT, Australia allocated black coal used for pulverised coal injection (consumed as a reductant) to the industrial processes and product use sector. This has resulted in a reallocation of black coal from *1.A.2.a iron and steel* to *2.C.1 metal production* from 2003 onwards, when pulverised coal injection was first used in Australia. However, there is some minor use of black coal for combustion purposes remaining in the Energy sector under *1.A.2.a iron and steel*. This coal is driving the solid IEF to be higher than

that of coke oven gas alone, as well as influencing the annual fluctuations observed in the solid IEF from 2003 onwards. Following the 2015 ERT recommendation, Australia provided additional information to improve the transparency on the activity data for black coal and coke oven gas fuel mix consumed in 1.A.2.a iron and steel sector. Table 3.12 shows the percentage of black coal/coke oven gas fuel mix within solid fuels.

Table 3.12 Percentage of black coal and coke oven gas fuel mix in 1.A.2.a

Years	per cent of coal	per cent of coke oven gas

2018	2	98
2019	1	99
2020	2	98

Liquid fuels

The liquid fuel CO₂ IEF is relatively low, driven by the dominant use of LPG (CO₂ EF of 60.2 Gg/PJ) compared to other liquid fuels with higher EFs. However, a sharp increase in the IEF in 2001 was the result of an increase in the use of diesel and fuel oil relative to the consumption of LPG. As LPG has a relatively lower CO₂ EF, the change in fuel mix resulted in an increase in the overall liquid CO₂ IEF.

1.A.2.c Chemicals: Emissions and IEFs for *chemicals* are influenced by the mix of end products which sequester carbon. The production mix of the Australian chemicals industry changes over time, resulting in a variable trend.

3.4.4 Source specific QA/QC

This source category is covered by the general QA/QC of the greenhouse gas inventory in Chapter 1.

3.4.5 Recalculations since the 2019 Inventory

Recalculations to 1.A.2 manufacturing and construction are detailed at the sub-category level in Table 3.13.

Revisions to the Australian Energy Statistics

A key reason for recalculations arises from revisions by DISER to the Australian Energy Statistics. The revisions to the Australian Energy Statistics are due to the incorporation of improved activity data available under the NGERs.

Recalculations were made in response to revisions in fuel consumption reported in the latest Australian Energy Statistics. Minor adjustments have been made to the following:

- Non-ferrous metals: wood and wood waste for the period 2009–2019
- Chemicals: LPG and petroleum products for the period 2015–2019.
- Other: Diesel consumed in the Construction sub-category for the period 2015–2019. This was an increase of 3.7 PJ in 2015 increasing up to 11.3 PJ in 2019.

3.4.6 Planned improvements

The Department will continue to look at applying revisions to the earlier part of the time series in response to future Australian Energy Statistics releases.

In response to a recommendation from a previous review report, a study was commissioned by the Department to investigate the appropriateness of the fuel characteristics for liquid fuel types. As a result, further analysis of Australian liquid fuel characteristics will be undertaken in the future to consider whether any changes are necessary.

An investigation is underway to determine the method for splitting the non-biomass fraction of waste fuels. Work is also underway to update the non-biomass waste tyre emission factors combusted for energy within NGER reporting. This work is expected to be implemented within the next NIR and will allow for enhanced accuracy and transparency.

3.5 Source category 1.A.3 Transport

3.5.1 Source category description

This source category includes emissions from the *transport* sector, comprising the civil aviation, road transportation, marine navigation, railways and 'other' categories.

Activity data on fuel consumption is sourced from the *Australian Energy Statistics 2021* (DISER 2021a). A number of mobile source categories have been allocated to the stationary source inventory because the current national data collection methods do not allocate this fuel to the transport sector but rather to the specific ANZSIC class in which it is used. In particular, emissions from miscellaneous off-road vehicles used in specific ANZSIC classifications (such as tractors and other farm vehicles, forestry vehicles, quarry trucks and front-end loaders, construction equipment, and forklifts) are allocated to the corresponding ANZSIC group and accounted for in sectors 1.A.2 and 1.A.4. More information on the assumed mobile components of stationary source is at section 3.2.2. Emissions from mobile utility engines (such as lawn-mowers, chain-saws, portable generators and mobile compressors) and military transport are reported in sectors 1.A.4 and 1.A.5 using the methodologies detailed in this sector.

Emissions from other off-road mobile source, however, such as unregistered trail bikes, recreation vehicles and competition vehicles are reported under 1.A.3.

3.5.2 Methodology

Like other energy sub-sectors, the methodology for 1.A.3 is based on the application of 'bottom up' approaches to the estimation of emissions. The estimation of non-CO₂ emissions from passenger and light commercial vehicles utilises a Tier 3 approach that depends on data on vehicle kilometres travelled, vehicle fleet characteristics and vehicle operating modes. Non-CO₂ emissions from civil aviation using aviation turbine fuel are estimated using a Tier 2 approach (with a Tier 1 approach applied to estimates of non-CO₂ emissions from domestic aviation using gasoline), which takes account of fuel consumed, landing and take-off cycles and Australian fleet characteristics.

Table 3.14 Summary of methods and emission factors: Transport

Source Category	CO ₂		CH ₄		N ₂ O	
	Method applied	Emission factor	Method applied	Emission factor	Method applied	Emission factor
1A3a Civil Aviation	T2	CS	T1/T2	CS/D	T1/T2	CS/D
1A3b Road Transportation - passenger, light commercial and heavy vehicles	T2	CS	T3	CS	T3	CS
1A3b Road Transportation - other	T2	CS	T1	CS	T1	CS
1A3c Railways	T2	CS	T1	D	T1	D
1A3d Water-borne Navigation (Domestic)	T2	CS	T2	CS	T2	CS
1A3e Other Transport	T2	CS	T1	D	T1	D
1A2g Other	T2	CS	T2	CS	T2	CS

Notes: T1 = tier 1, T2 = tier 2, T3 = tier 3, CS= Country-specific, D= IPCC default.

General methodology

The emission estimate of a greenhouse gas from fuel combustion in the engines of a mobile source, using a specified fuel type, is calculated by:

$$E_{(i)ijk} = A_{ijk} \times F_{(i)ijk} \quad (3.3)$$

Where $E_{(i)ijk}$ is the emission of greenhouse gas l in gigagrams (Gg) from a mobile vehicle and age class i and technology j using fuel type k

A_{ijk} is the activity level, where u refers to either energy consumption in petajoules (PJ) or to distance travelled in kilometres (km)

$F_{(i)ijk}$ is the EF, in units of grams of gas l emitted per megajoule of energy use (g/MJ) for CO₂ and SO₂, and grams of gas l emitted per kilometre travelled (g/km) for other non-CO₂ gases

Fuel consumption data for the *transport* sector are taken from *Australian Energy Update*. The main adjustments applied to energy consumption data allocates some fuels to off-road, residential and military fuel uses (reported in Table 3.14).

The allocations of fuel to military transport in 2008, 2009 and 2010 are informed by direct reporting of fuel consumption by the Australian Department of Defence (2010–2012).

Allocations for 2011, 2012 and 2013 are based on energy use data published by the Australian Government in accordance with its *Energy Efficiency in Government Operations (EEGO) Policy* (AGO 2007). This required the preparation of an annual whole-of-government report on the total energy use and estimated greenhouse gas emissions of Australian Government departments and agencies, and presented in the report *Energy use in the Australian Government's operations* using information reported to the Department of Resources, Energy and Tourism from all government departments and agencies – including the Department of Defence. Allocations for 1995–2007 are linearly extrapolated between the reported data points in 1994 and 2008.

This reporting was discontinued, and the allocations of fuel to military transport from 2008 onwards are informed by direct reporting of fuel consumption by the Australian Department of Defence.

Civil aviation (1.A.3a)

The estimation of CO₂ emissions from civil aviation is undertaken using a Tier 2 methodology and EFs given in Tables 3.2 and 3.3.

Non-CO₂ emissions from domestic civil aviation from fuel use are estimated using both a Tier 1 and a Tier 2 methodology. For larger aircraft operating on aviation turbine fuel, emissions are calculated as a function of both the landing/take-off cycles (LTOs) and of cruise emissions for both domestic and international aircraft.

Small aircraft operating on aviation gasoline make up a small portion of aviation emissions, and are estimated using a Tier 1 approach and IPCC default EFs.

The Tier 2 estimation of emissions from landing and take-off cycles of larger aircraft operating on aviation turbine fuel requires data on the number of LTO cycles at Australian airports; data on the profile of the Australian aviation capital stock or fleet; and EFs by type of aircraft. The data required for the total yearly LTO for the domestic and international aircraft are available from the Bureau of Infrastructure, Transport and Regional Economics (BITRE 2019) within the Department of Infrastructure, Transport, Regional Development and Communications.

The Australian aviation fleet profile is developed using the Australian Aircraft Register which is available from the Civil Aviation Safety Authority (Table 3.15). EFs for each aircraft type are taken from IPCC 2006 and are used to estimate weighted average LTO cycle EFs for the domestic/interstate and international aviation fleets (Table 3.16). These EFs most accurately reflect the technology and aircraft types currently in the Australian aircraft fleet. In a couple of instances EFs are not available for a certain aircraft type. These aircraft are allocated to the aircraft type, for which an EF exists, that most closely reflects the aircraft's engine characteristics.

The estimation of cruise emissions is a function of fuel use, after deduction of fuel consumption required for the LTO cycles, and cruise EFs. Data on the yearly fuel consumption for domestic and international activity are available from DISER 2021a. Cruise EFs are taken from IPCC (2006) (Table 3.17), with N₂O being a weighted average EF for the Australian domestic aircraft fleet.

The methodology is applied to each of the eight Australian states and territories (with the exception of the Australian Capital Territory, which, due to the unavailability of disaggregated fuel consumption data, is included in estimates for the state of New South Wales). Differences in emission estimates across the States principally reflect differences in fuel consumption and both the number of LTO cycles and the relative importance of major interstate movements relative to regional LTO cycles, which impacts on the aircraft type that use State airports. National emissions are estimated as the sum of the State and Territory emissions.

For small piston engine aircraft operating on aviation gasoline fuel, non-CO₂ emissions are estimated using a Tier 1 approach. This method applies default EFs (IPCC (2006) for all fuels and aircraft types) to all aviation gasoline fuel consumed by state (Table 3.18).

Emissions from international aviation are also estimated, but are reported as a Memo item only, by international agreement.

Activity data for international bunkers is estimated by the Department as part of the Australian Energy Statistics. The Department also uses data from the *Australian Petroleum Statistics* (DISER 2021b) which publishes monthly national and state petroleum statistical information while sales of aviation turbine fuel, diesel and fuel oil for domestic and international uses are published on a quarterly basis. The Australian Petroleum Statistics explanatory note, which informs company reporting, states that the dissection of international and domestic fuel consumption is made according to the predominant activity of each operator.

Independent of the national inventory, the Department of Infrastructure and Regional Development (DIRD) has developed a software tool to compute and track the carbon footprint associated with aircraft fuel uplifted in Australia. The DIRD completed an assessment of the robustness of their results by comparing their calculated values with the APS. Their results showed that for domestic aviation, computed CO₂ estimates using the software tool and inventory estimates differed by 0.1 per cent in 2013 for domestic consumption, and 2.1 per cent for international consumption in 2013. This is considered to be an excellent independent verification of the estimates.

DIRD (now the Department of Infrastructure, Transport, Regional Development and Communications) no longer undertakes modelling of aircraft emissions independently. Whilst future comparisons will not be possible, the several years it was possible have served to validate methods that continue to be applied in the inventory.

Table 3.15 The Australian aircraft fleet, 2020, and emission factors by type of aircraft

Road transportation (1.A.3.b)

Like the aviation sector, the estimation of CO₂ emissions from the road transport sector is based on a Tier 2 method with EFs given in Table 3.2. The estimation of non-CO₂ emissions is based on a Tier 3 method, with the emission estimates dependent on the type of vehicle, the age of the vehicle capital stock, technology, operating mode (cold versus hot) and road type (urban versus non-urban). Activity data is expressed in terms of vehicle kilometres travelled and EFs are expressed in g/km. The methodology is applied to each of the eight Australian States and Territories. Differences in emission estimates across the States and Territories principally reflect differences in fuel consumption and the impacts on non-CO₂ emission estimates of differentials in the age distribution of each State and Territory's vehicle fleet. National emissions are estimated as the sum of the State and Territory emissions (see Figure 3.12).

Figure 3.12 Methodology for the estimation of non-CO₂ emissions from passenger and light commercial vehicles

Passenger and light commercial vehicles, heavy vehicles and buses (1.A.3.b i-iii)

CO₂ emissions from all vehicle fuel sources have been estimated based on the quantity of fuel consumed by the CO₂ EF specific to that fuel and the proportion of that fuel which is completely oxidised.

$$E_{ijk} = A_{ijk}^{u=1} \times (F_{(i)k} \times P_k) \quad (3.4)$$

Where $F_{(i)k}$ is the CO₂ EF applicable to complete oxidation of fuel carbon content for fuel type k (where k=petrol, diesel and LPG)

P_k is the proportion of fuel that is completely oxidised upon combustion

A_{ijk} is the activity data for vehicle type i with emission control technology j and fuel type k (and where u=1 for fuel consumption in each Australian State)

The CO₂ EFs and oxidation factors for each fuel are summarised in Tables 3.2 and 3.3.

For all vehicles besides motorcycles consuming automotive gasoline, ethanol, diesel and LPG, non-CO₂ emissions for each age class are estimated based on vehicle kilometres travelled (VKT) in each State or Territory; the profile and age of the vehicle capital stock in each State; the penetration of catalytic control technology; mode of operation and road type; and vehicle and fuel specific EFs.

It is assumed that all light duty vehicles go through a cold start phase for each trip which is associated with higher emissions due to engine and catalyst temperatures that are below optimum. The number of cold starts is derived from total VKT and an average trip length sourced from Pekol Traffic and Transport (Pekol Traffic and Transport 2021). Average trip length by State and Territory and by vehicle type is estimated for each year throughout the time series. This data replaced static average trip length of 10km that was previously applied across States and Territories and vehicle types. Average trip length data is listed at Table 3.A.20. A cold-start duration of 3km (as cited in IPCC 2006) is used to determine the total cold start VKT. This is subtracted from total VKT to derive an adjusted total VKT value.

EFs vary by road type (urban versus non-urban) to reflect the different driving conditions and engine operating profiles. Distance travelled is disaggregated into urban and non-urban VKT in each State and Territory and by vehicle type (Pekol Traffic and Transport 2021).

Vehicles using automotive gasoline, ethanol, diesel and LPG are further classified by age of vehicle using data contained in ABS 2021. The divisions in the vehicle fleet enable differences in emissions control technology and differences in fuel efficiency across age classes to be factored into the emissions estimation. Passenger vehicles and light commercial vehicles manufactured and sold in Australia before 1976 are assumed to have no emissions control equipment. The 1976–1985 group uses a variety of non-catalytic control (such as exhaust gas recirculation) and the 1985–1997, 1998–2003, 2004–2005 and the post-2005 groups use catalytic control.

In general, non-CO₂ exhaust emissions from vehicles have been calculated by the following form of equations:

$$E_{(l)ijk} = A^{u=2}_{ijk} \times EF_{(l)ijk} \quad (3.5)$$

Where l = non-CO₂ gases; $A^{u=2}$ for vehicle kilometres travelled and k = automotive gasoline, diesel, and LPG;
 $EF_{(l)ijk}$ is the exhaust EF for gas l from vehicle type i and age class j using fuel type k for urban and rural operation in each state or territory and where vehicle distances travelled during the hot-engine phase of operation are related to energy consumption levels using:

$$A^{u=2}_{ijk} = A^{u=1}_{ijk} / R_{ijk} \times D_k \quad (3.6)$$

Where $A^{u=2}_{ijk}$ is the distance travelled for vehicle type i and age class j , using fuel type k = automotive gasoline, diesel, and LPG
 R_{ijk} is the average rate of fuel consumption (in l/km, given in Tables 3.A.15–3.A.17) for vehicle type i and age class j , using fuel type k
 D_k is the energy density of fuel type k (in MJ/L)

and where

$$EF_{(l)ijk} = (ZKL_{ijk} + DR_{ijk} \times C_u mVKT_{ijk}) \quad (3.7)$$

Where $EF_{(l)ijk}$ is the EF for gas l from each vehicle type i and age class j , using fuel type k = automotive gasoline, diesel, and LPG
 ZKL_{ijk} is the zero kilometre level emissions of a gas l from vehicle type i and age class j
 DR_{ijk} is the deterioration rate for vehicle type i and age class j
 $C_u mVKT_{ijk}$ is the cumulative VKT for vehicle type i and age class j , and fuel type k , in each state or territory

and where

$$C_u mVKT_{ijk} = \sum_{t=1-n} A^{u=2}_{ijk} \quad (3.8)$$

Where $A^{u=2}_{ijk}$ is the average distance travelled (in km) by vehicle type i and age class j , using fuel type k = automotive gasoline, diesel, and LPG in each State or Territory summed over time

Cold start emissions are derived using equation 3.9:

$$E_{cs,ijk} = CS_{ijk} \times EF_{c,ijk} \quad (3.9)$$

Where $E_{cs,ijk}$ are the cold start emissions for vehicle type i and age class j , using fuel type k = automotive gasoline, diesel, and LPG
 CS_{ijk} is the number of cold starts for vehicle type i and age class j , using fuel type k = automotive gasoline, diesel, and LPG
 $EF_{c,ijk}$ is the cold start EF (g/start) for vehicle type i and age class j , using fuel type k = automotive gasoline, diesel, and LPG

Data on fuel consumption for individual vehicle types is derived from DISER 2019 and ABS (2019). The data on fuel consumption rates are taken from ABS (2019). The profile and age of the passenger vehicle stock in each State and Territory required for equation 3.7 is taken from ABS (2019). The vehicle stock from each historical year varies largely due to vehicle sales from each particular year, which in turn is largely driven by the prevailing economic conditions. For example the vehicle stock in 1991 is lower than surrounding years as a result of lower vehicle sales impacted by an economic recession affecting Australia at the time. Data required for estimating VKT for individual vehicle and age classes are given in Tables 3.A.15 to 3.A.17.

Emissions of CH₄ from motor-vehicles are a function of the emission and combustion control technologies present as well as vehicle operating conditions. EFs chosen for passenger and light commercial vehicles were obtained from Australian sources where these were available and applicable to the vehicle fleet and its various modes of operation and fuel types (see Tables 3.A.5–3.A.10). A major empirical study (*Second National In Service Emissions Study*) of emissions from the operation of light duty petrol vehicles was undertaken in 2009. The results of this study were analysed for the national inventory (Orbital Australia 2010). The study directly measured emissions from 347 petrol passenger vehicles and light commercial vehicles manufactured from 1994–2009. The 347 vehicles represented four ADR (Australian Design Rule, DIRD 1969–1988) age groupings.

A petrol Composite Urban Emissions Drive Cycle (CUEDC) was developed as a means of better representing driving under Australian conditions. All vehicles undertook a hot start CUEDC while a subset of the vehicles also undertook a cold start. Emission measurements were allocated to hot urban, non-urban and cold driving conditions. Total hydrocarbon, CO, NO_x, CO₂ and CH₄ emissions were measured from bag samples. EFs (Table 3.A.5–3.A.8) and deterioration rates (Table 3.A.11) were derived for ADR groupings for each gas and each driving condition.

Using the EFs and deterioration rates a zero kilometre EF was derived. Results were assessed by cross-referencing the generated results to the zero kilometre capability of the vehicle fleet. This reference point is based on the assumption that at zero kilometres the vehicles were generally in compliance with emission standards of the day and that in general the deterioration over the ADR specified period is indicated to be in line with automotive engineering expectations. Orbital Australia (2010) details these checks.

Orbital Australia (2011b) was used to extend the direct measurement approach outlined above to older vehicles by utilising measurements taken for other studies including the pilot phase of the *Second National In Service Emissions Study* and the *First National In Service Emissions Study*. The outcomes from this report provided updated EFs and deterioration rates for petrol passenger vehicles and light commercial vehicles manufactured between 1986 and 1993. The use of disaggregated, country-specific EFs expressed in terms of emissions per kilometre travelled is consistent with the IPCC Tier 3 methodologies. For vehicles not covered by the studies outlined above the choice of US versus European default factors has been dictated by the exhaust emission standards in the Australian Design Rules (ADR) applicable to each particular vehicle vintage. Australian Design Rules have been harmonised with European Standards since 1996 in heavy duty vehicles. Therefore the IPCC default factors used for post-1995 heavy duty vehicles are based on European data (COPERT IV, EEA 2011). Prior to the harmonisation with European standards, US Federal Test Protocol standards were used as the basis for ADRs. Therefore USEPA default factors cited in IPCC 2006 are used for earlier vehicle vintages where required.

Australian design rules applied to Australia's vehicle fleet, their date of introduction and the European sources for these standards are outlined in Table 3.19. The age-band structure of the motor vehicle emission model is based on the applicability of a given ADR to a given vehicle vintage.

Table 3.19 Australian petrol passenger car exhaust emission standards, Australian heavy duty diesel exhaust emission standards

Australian Standard	Year introduced	Source standard
Petrol passenger vehicles		
ADR 79/00	2004	Euro 2
ADR 79/01	2006	Euro 3
ADR 79/02	2010	Euro 4

ADR 79/04	2016	Euro 5
Heavy duty diesel exhaust		
ADR 70/00	1996	Euro 1
ADR 80/00	2003	Euro 3
ADR 80/01	2005	Euro 4
ADR 80/02	2008	Euro 4
ADR 80/03	2010	Euro 5

Source: DIRD (2015).

There are no country-specific CH₄ EFs available for heavy-duty vehicles. These EFs have been taken from DCC 2006 or IPCC 2006 as indicated in Table 3.A.7. CH₄ EFs for post-2005 vintage vehicles (Euro 3) have been derived based on the Euro 1 COPERT IV EF and an emission reduction factor according to the method in EEA 2009. A summary of the EFs used to estimate CH₄ emissions from the Australian petrol, diesel, LPG and ethanol driven passenger and light commercial vehicle fleets, as well as their respective sources, are presented in Table 3.A.6.

Emissions of non-CO₂ exhaust gases may increase as the vehicle ages due to the gradual wearing of components, poor maintenance, deactivation of catalyst materials, removal of emission control equipment, oxygen sensor failure, or modification of the engine. The rate of increase in emissions per kilometre per vehicle kilometres travelled is the deterioration rate. Deterioration rates are positive, indicating that emissions increase with mileage. Deterioration rates for each gas, vehicle design category and vehicle type combination are calculated by fitting a linear regression to the scatter of directly measured emissions by vehicle kilometres travelled.

For petrol passenger vehicles and light commercial vehicles manufactured prior to 1986 a study by EPA NSW (1995) analysed the combined emission test databases of EPA NSW and EPA Victoria to determine deterioration rates and zero VKT (i.e. new car) emissions for the two States' combined fleet. For vehicles manufactured from 1986 onwards the deterioration rates are taken from the Orbital Australia 2010 and Orbital Australia 2011b.

The inventory model is regularly updated to allow separate deterioration rates to be applied to passenger vehicles and light commercial vehicles.

The deterioration rates derived in the Orbital reports are based on a study of petrol vehicles. A separate study was undertaken to assess the appropriateness of applying the petrol deterioration rates to other fuels (Orbital Australia 2011c). Limited information was found on the deterioration rates of many vehicles using other fuels however there was evidence that the deterioration rate of diesel passenger vehicles is less than petrol vehicles. Based on the available information Australia has applied the petrol deterioration rates to the diesel and ethanol consumed in passenger and light commercial vehicles which is believed to be a conservative approach. The deterioration rates used to derive EFs for the passenger and light commercial vehicle fleet are shown in Table 3.A.11. The data shows no evidence of deterioration in the level of N₂O emissions, therefore a deterioration rate of 0 is used.

The majority (345 out of 347) of vehicles tested in the *Second National In Service Emissions* study had a VKT between 0 and 300,000km. Most of the deterioration rates used in the transport model are sourced from this data set. Therefore Australia has applied a limit to the application of the deterioration rate based on total vehicle kilometres travelled. This limit is applied at an accumulated average VKT of 300,000km per vehicle.

N₂O EFs for Australia's petrol-fuelled passenger vehicle fleet are based on CSIRO testing (Weeks *et al.*, 1993) of vehicles of vintage up to 1993, fitted with a range of emissions control technology. Test data on vehicles not fitted with catalysts are used for the pre-1976 and the 1976–85 age groupings and a weighted average of the catalyst equipped emissions used for the 1985–1997 and the post-1997 vehicle fleet. The EFs in Weeks *et al.* are comparable to those reported in IPCC (2000) and by the USEPA and COPERT IV. N₂O EFs for light duty petrol vehicles of vintage 1994 onwards are estimated in the Orbital Australia 2010 report on NISE 2 data.

Australian emissions standards as set out in Australian Design Rules (ADRs) have tended to lag those applied in Europe and the United States (see Table 3.19). Consequently, the types of emissions control technology employed in Australia also tend to lag as these are introduced in order to comply with the emissions standards.

The EFs used to estimate N₂O emissions from the Australian petrol, ethanol, diesel and LPG driven passenger and light commercial vehicle fleets, as well as their respective sources, are presented in Table 3.A.9.

There are no country-specific N₂O EFs available for heavy-duty vehicles. These EFs have been taken from DCC 2006 and IPCC 2006 as indicated in Appendix Table 3.A.9.

EFs from the *2006 IPCC Guidelines* are used in the road transportation sector when they are the most appropriate factors for the vehicle standards and technology that exist in the Australian road transport fleet.

Australia's IEF for CH₄ from liquid fuels (Fuel Combustion sectoral approach) is most influenced by the contribution of CH₄ emissions for Road Transportation, Cars, and Petroleum. CH₄ implied emission factors for Road Transportation, Cars, and Petroleum have been trending down since the mid-1990s as the inventory reflects improved vehicle emissions control technology performance in the Australian fleet (Figure 3.13).

Diesel oil implied emission factors, notably for N₂O, tend to fluctuate due to the emission factors for N₂O being highly different for medium and heavy trucks and buses, resulting in implied emission factor fluctuations according to their proportional contributions.

The Australian fleet has a relatively high non-CO₂ emissions profile due to the lag behind source emission standards applied in Europe and the United States – Consequently, the types of emissions control technology employed in Australia lags as these are introduced in order to comply with the emissions standards. This is compounded in the current fleet by a relatively slow fleet turnover and transition to vehicles with improved emission control technologies.

Motorcycles (1.A.3.b.iv)

The estimation of emissions for motorcycles is given by equations 3.4 and 3.5. Fleet average EFs for motorcycles are provided in Table 3.A.13.

Evaporative fuel emissions (1.A.3.b.v)

Road vehicles using automotive gasoline emit NMVOCs both from the exhaust and through evaporation. The evaporative NMVOC emissions include:

- Running losses resulting from evaporative emissions released during engine operation. Running losses occur when the capacity of the vapour control canister and purge system is exceeded by the vapour generation rate and are greatest at low average vehicle speeds. Running losses vary with the age and type of control system of the vehicle and the trip duration;
- Hot soak losses resulting from evaporation of fuel at the end of each trip. These emissions bear little relation to the VKT for an individual vehicle. A more realistic activity on which to base these emissions is the number of trips an average vehicle would make in a given time period;
- Diurnal losses resulting from vapour being expelled from fuel tanks due to ambient temperature rises. These emissions are strongly dependent on the Reid Vapour Pressure (RVP) of the fuel, the daily ambient temperature changes and where the vehicle is parked during the day. Emissions will vary significantly between identical vehicles in different geographical regions. Diurnal emissions only occur when the temperature is rising; and
- Resting losses resulting through the permeation of fuel through rubber hoses or open bottom carbon canisters. Resting losses have often been included in measurements of hot soak, diurnal and running losses (USEPA, 1991a).

EFs for evaporative emissions for each of the three passenger vehicle age classes have been estimated for average Australian temperatures and fuel properties and are presented in Table 3.A.19.

Urea-based catalysts (1.A.3.b.vi)

Heavy and passenger vehicles operating on diesel fuel in Australia include later year model vehicles using urea catalyst technology (selective catalyst reduction SCR) to reduce NO_x emissions.

Australian emission standards mirror Euro emission limits and approaches and do not dictate a particular technology with emission standards met by a range of technological approaches which includes SCR both in heavy and passenger transport.

Australia made a preliminary estimate of emissions from Urea based catalysts and considered it to be an insignificant source.

This assessment was made by considering the potential emissions from heavy vehicles. Australia has around 36,000 diesel heavy vehicles operating in 2018 that conform to Euro IV and Euro V – not all of these are known to employ SCR technology (the UK for example assumes 75 per cent are so equipped), but to be conservative it was assumed all 36,000 vehicles use the technology.

The EMEP/EEA Guidebook suggests it is assumed that urea consumption is 3–4 per cent of fuel consumption for a Euro IV HGV and bus and 5–7 per cent for a Euro V HGV and bus – again to be conservative Australia applied 6 per cent to both classes.

With these assumptions, it was estimated that there are 23kt CO₂ attributed to heavy vehicles in Australia (0.004 per cent of the total inventory).

Australia applied Euro emission standards, however there is a lag of several years. Combined with a historically low uptake of diesel for passenger cars compared to European markets, emissions associated with the use of SCR in passenger cars is expected to be a small fraction of that from heavy vehicles.

Railways (1.A.3c)

Emissions are estimated using Tier 2 methods described by equations 3.1 and 3.2. CO₂ EFs are reported in Table 3.2 and non-CO₂ EFs are reported in Table 3.20. Given data on the composition and engine types in the local fleet, an average fleet EF has been calculated using the individual engine EFs in USEPA (1992). Data on fuel consumption is taken from the Australian Energy Statistics.

Source: (a) USEPA (1995a). (b) Lloyd's Register of Shipping (1995, and previous issue). (c) IPCC 2006).

Water-borne navigation (1.A.3d)

Emissions are estimated using Tier 2 methods described by equations 3.1 and 3.2. CO₂ EFs are reported in Table 3.2 and non-CO₂ EFs are IPCC 2006 Default values or taken from Lloyds Register of Shipping 1995 and are reported in Table 3.20. As discussed in section 3.2.1, where IPCC 2006 defaults are adopted their appropriateness for Australia has been validated by Orbital Australia (Orbital 2011a) and are therefore considered to be country specific emission factors.

Emissions from international bunker fuels are also estimated, but are excluded from national emission inventory aggregates by international agreement. Activity data for international bunkers is estimated by the Department as part of the Australian Energy Update. The Department also uses data published in the *Australian Petroleum Statistics* (APS, DISER 2021b) series. Monthly national and state petroleum statistical information are published in the Australian Petroleum Statistics. Sales of aviation turbine fuel, diesel and fuel oil for domestic and international uses are separated on a quarterly basis.

The Australian Petroleum Statistics explanatory note, which informs company reporting, states that the distinction between international and domestic fuel consumption data is undertaken according to the predominant mode of usage by the consumer.

Pipeline transport (1.A.3.e.i)

Australia has an extensive system of long distance natural gas transmission pipelines. Emissions are estimated using Tier 2 methods described by equations 3.1 and 3.2. CO₂ EFs are reported in Table 3.2. Data on fuel consumption is taken from the Australian Energy Statistics.

3.5.3 Uncertainties and time series consistency

The Tier 1 uncertainty analysis in Annex 2 provides estimates of uncertainty according to IPCC source category and gas. Time series consistency is ensured by the use of consistent models, model parameters and datasets for the calculations of emissions estimates. Where changes to EFs or methodologies occur, a full time series recalculation is undertaken.

3.5.4 Source specific QA/QC

This source category is covered by the general QA/QC of the greenhouse gas inventory in Chapter 1 and the fuel combustion specific QA/QC outlined in section 3.2.6.

The primary sources of activity data for this sector are the Department of Industry, Science, Energy and Resources (DISER) and the Australian Bureau of Statistics (ABS). These two organisations have systematic quality assurance programmes in place. In addition, there are also a number of critical user organisations and alternative data sources available for this sector.

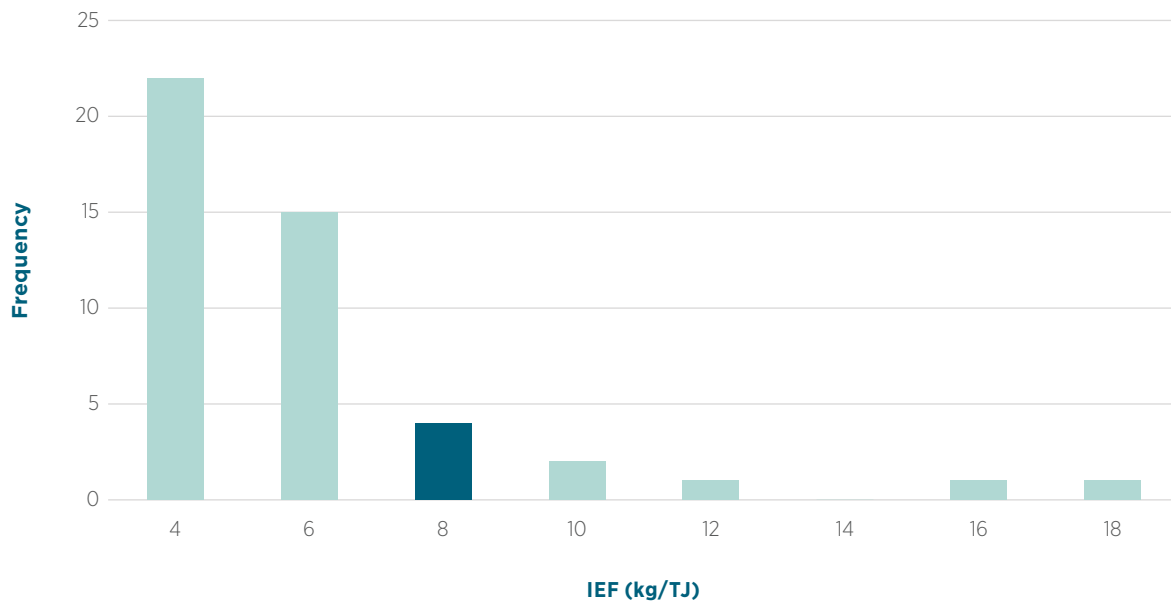

Comparisons of IEFs and with international data sources are conducted systematically for the Australian inventory. In the 2020 inventory submission it was found that the IEF for CH₄ from the combustion of liquid fuels in Australia (7.8 kg CH₄/TJ) was higher than those of other Annex 1 parties (4.8 kg CH₄/TJ) (Figure 3.13).

Three studies (Orbital 2010, 2011b and 2011c) have improved the emission estimates for fuel combusted by Australian passenger vehicles and light commercial vehicles (the largest contributors to CH₄ fuel combustion emissions).

Throughout the time series, Australia has introduced progressively stricter emission standards for new motor vehicles sold in Australia. Over time, the fleet composition reflects the improved performance of larger amounts of vehicles operating with sophisticated catalysts and efficient fuelling systems. The steady rollout of these technologies into the fleet has been reflected in a steady decrease in the emissions of CH₄ and other unburnt hydrocarbons from gasoline engines in particular.

Further improvements will be implemented for the road transport model as outlined in section 3.5.6.

Figure 3.13 2019 methane implied emission factor (IEF) from liquid fuel combustion (kg/TJ) for Annex I countries and 2020 IEF for Australia

Independent emissions modelling

Independent assessments of emissions from air and road transport are undertaken in Australia, providing independent verification of emission estimates prepared in accordance with IPCC 2006.

The Department of Infrastructure and Regional Development developed a software tool to compute and track the carbon footprint associated with aircraft fuel uplifted in Australia, providing an assessment of the robustness of their results by comparing their calculated values with the APS. Their results showed that computed CO₂ estimates using the software tool and inventory estimates differed by 0.1 per cent in 2013 for domestic consumption, and 2.1 per cent for international consumption in 2013.

Additionally, an Australian specific application of COPERT has been developed by the University of Queensland for use in modelling air quality emissions from the Australian road vehicle fleet. Included in this is the ability to model greenhouse gas emissions.

Emission estimates for CO₂ aligned well with the National Greenhouse Accounts, with less than 4 per cent difference in emissions from road transport.

3.5.5 Recalculations since the 2019 Inventory

- Recalculations have been made in response to revised AES data for fuel consumption;
 - 2017–2019 road transport for gasoline,
 - 2019 rail transport for diesel,
 - 2018–2019 domestic marine for diesel, and 2017–2018 for fuel oil,
 - 2015–2018 international marine for fuel oil, and
 - 2015–2018 domestic and international aviation for turbine fuel,

Removal of LPG fuel that was previously allocated to rail transport following further investigation that showed it was not used directly in transport activities. This change impacts estimates in 1990–1993 and 2008 onwards. A similar process was conducted for natural gas which has effected emissions in 2018.

The expansion of non-CO₂ estimates from ethanol consumption to domestic marine and off road machinery impacting emissions between 2007 and 2019.

3.5.6 Planned improvements

A number of mobile source categories are allocated to the stationary source in the inventory because the current national data collection methods do not allocate this fuel to the transport sector but rather to the specific ANZSIC class in which it is used. The Department will continue to monitor the NGER data to investigate the magnitude of these emissions and whether the reliability, completeness and accuracy of the data are adequate to inform a reallocation of these emissions from the stationary sectors to the transport sector.

The Orbital Australia reports (Orbital Australia 2010 and Orbital Australia 2011b) provided detailed vehicle testing data that is at a greater level of disaggregation than is currently supported in the national inventory model. The department plans to investigate and apply updates, as appropriate, to the issues listed below in future inventory submissions:

- Within the passenger vehicle groups, EFs for large SUVs (sport utility vehicles) can vary significantly between specific vehicle make/models depending on the original ADR to which they are certified. These factors are also significantly different to the other vehicle sub-types in the passenger vehicle group. Separate EFs and DRs for SUV-Large are available. The Department will investigate whether all the activity data is available to support further disaggregation of vehicle classifications in the next annual inventory submission; and
- Passenger vehicle and light commercial vehicle EFs from the NISE 2 dataset are available for an additional drive cycle (hot extra urban). The Department will investigate whether the required data is available to support the further disaggregation of drive cycles in the next inventory submission.

Australia continues to investigate EFs for new petrol passenger vehicles to take account of the latest exhaust emission standards adopted in Australia.

Australia will investigate sources with the aim to update non-CO₂ emission factors for domestic navigation. Current factors come from Lloyd's Register of Shipping which has been noted by the latest ERT as being possibly out of date. Noting that it is a minor source of emissions this analysis will be prioritised accordingly.

Australia will investigate methods to disaggregate and reallocate emissions from lubricant use in two-stroke engines, and subsequently estimate and report CH₄ and N₂O emissions from lubricant use in two-stroke engines in category 1.A.3.b.

3.6 Source category 1.A.4 Other Sectors

3.6.1 Source category description

Source category *1.A.4 other sectors* is an aggregation of the following sources:

- Commercial/Institutional – a diverse category which includes direct emissions from water utilities, accommodation, communications, finance, insurance, property and business services, government and defence, education, health and wholesale and retail trade;
- Residential – emissions from fuel combustion in households, including lawnmowers; and
- Agriculture, forestry and fisheries – emissions from fixed and mobile equipment.

The Australian Energy Statistics report energy consumption for economic sectors is defined using the Australia New Zealand Standard Industrial Classification (ANZSIC). The mapping of ANZSIC codes against IPCC classifications is complete and given in Table 3.22. Only the petroleum from ANZSIC Subdivision 50–53 Other transport, services and storage is included in this category. The natural gas consumption is accounted for within the Transport sector (Natural Gas Transmission) sub-category. Similarly, only the natural gas consumption from sub-category 47 Railway Transport is included in this category. Any other fuel consumption within sub-category 47 is assumed to be accounted for within sector I.A.3.

3.6.2 Methodology

The methodology for this sector consists of tier 2 approaches and country specific CO₂ EFs. Non-CO₂ EFs have been calculated using a sectoral equipment-weighted average approach.

CO₂ emission are reported in Table 3.1. Activity data are taken from the AES published by the Department (DISER 2020). Non-CO₂ EFs for this sector, by ANZSIC Division, are reported in Appendix Table 3.A.3.

Residential – biomass combustion (1.A.4)

The *Residential* sector also includes specific treatment of the use of firewood and also in the combustion of fuels in mobile equipment such as lawnmowers.

This category is characterised by the use of wood in residential wood heaters. Emissions are modelled using an advanced tier 2 approach which takes into account factors such as wood heater technology and replacement of older models, user operation and Australian wood.

The estimation of emissions from residential firewood use requires a more complex approach to the estimation of emissions from fossil fuels reflecting information on heater design (technology type) and the operation of wood-burning appliances, which influences the mix of emissions per kilogram of firewood consumed.

The proportion of Australian households choosing firewood as their main heating fuel peaked in the early 1990s and has decreased slowly since then. New appliances with lower emissions of some greenhouse gas species came on the market in the early 1990s and they have gradually been replacing older, non-certified heater models. Poor user behaviour, which significantly increases emissions of pollutants, has been the target of education campaigns and, in the past few years, programs have been aimed specifically at households with excessive visible smoke. This has led to improved appliance use.

The residential wood heater methodology has been developed for Australian conditions (Todd 2003, 2005 and 2011). This methodology was recently updated (Todd 2011) to account for the latest information and trends. The model was validated against recent field studies of emissions from wood heaters used in Australian households and resulted in a minor increase to the CH₄ EF over the complete time series along with a small decrease in the CO₂ EF. The methodology incorporates factors such as appliance type and certification, wood type and moisture content and user behaviour. The composition of gaseous and particulate emissions when burning eucalypt firewood in typical Australian appliances is based on Gras (2002). A schematic diagram showing the methodology process is shown in Figure 3.14, and is also summarised in the algorithm below:

$$E_{k,n} = F_n \times S \times W \times f_{nk} \{ \sum PEF_n \} \quad 3.10$$

- Where
- $E_{k,n}$ = emission of greenhouse gas k in year n
 - F_n = amount of fuel combusted (i.e. firewood use) in year n
 - S = softwood use correction factor
 - W = wet wood correction factor
 - f_{nk} = formula linking the greenhouse gas EF for gas k to the particulate EF.
 - PEF_n = weighted particulate EF for year n, which is summed over the mix of appliances and operator behaviour for that year, with l = 1 to 8
 - l(1) certified wood heater correctly operated
 - l(2) certified wood heater carelessly operated
 - l(3) certified wood heater very badly operated
 - l(4) non-certified wood heater correctly operated
 - l(5) non-certified wood heater carelessly operated
 - l(6) non-certified wood heater very badly operated
 - l(7) masonry open fireplace
 - l(8) factory built (metal) open fireplace

Description of factors

Certified and non-certified heater

Emission factors

A base CH₄ EF for certified wood heaters of 261.3 Mg/PJ has been developed by Todd (2005). It has been derived from a large database on particulate emissions from heaters meeting the requirements of Australian Standard AS4013. Over 250 different heater models have been tested at the two NATA certified (National Association of Testing Authorities) laboratories in Australia, producing a database of over 2250 individual emission tests (heaters must have three repeat tests at each of high, medium and low burn rates).

A base CH₄ EF of 462.5 Mg/PJ has been applied to non-certified heaters, through the application of a factor of 1.77 to the certified wood heater EF. Todd (2005) based this approach on comparisons between US emission tests of non-certified heaters (referred to as 'Pre-Phase I Non-Catalytic Heaters' in US literature) and certified heaters (referred to as Phase II Non-Catalytic Heaters) (USEPA 1996). The Australian emission test for wood heaters has differences to the US test (both in test fuel, and testing procedure); however, the Australian Standard was cross-checked with two models of heater that had passed both the US (Phase II) and found to be generally similar. Thus the US ratio has been applied to Australian heaters.

Mix of certified and non-certified heaters and open fireplaces

A survey of households in 2000, carried out as part of a CSIRO study (Gras, 2002), found that 40 per cent of heaters were less than 6 years old (i.e. installed in 1994 or later). Taking into account the number of open fireplaces also in use (derived by Todd 2005 from a 1999 ABS survey), certified wood heaters accounted for 30.6 per cent of all wood-burning appliances in 2000. The population of certified wood heaters has been decreased linearly to 1994, where it is zero (Todd 2005). Todd (2011) extended the time series to 2010 based on data recent wood heater sales numbers from the home heating association.

Operator behaviour

Emission factors

Three operator classifications have been adopted for these calculations.

- r) 'Good' operation means a certified heater will perform as it did in the laboratory test.
- s) 'Careless' operation (or poor operation) refers to operators who pay some attention to heater performance, but are not well enough informed. A survey in Tasmania (Todd 2001) suggested at least half the heater owners fall into this category. Careless operation has been assigned EFs 2 times greater than for good operators, applying to both certified and non-certified heaters (expert judgement by Todd 2005).
- t) 'Very poor' operation refers to heater operators that regularly run the heater with a slow, smouldering fire. Todd (2001) indicates 10 per cent of households with wood heaters are in this category. The increase in emissions compared to a well-operated heater has been set at a factor of 5 based on a small number of laboratory tests (Todd 2005).

Proportion of well/poorly operated wood heaters

The proportion of good, careless and very poor wood heater operators for 2000 was set by Todd (2005) and modified by Todd (2011) at 0.5, 0.4 and 0.1 respectively. This is based on surveys in 1999 and 1997 that showed most households thought they operated their heaters correctly, but more detailed questioning showed that few did everything correctly. National TV campaigns (in 1997 'Breathe the Benefits') and a wide range of other education campaigns at state level suggest user behaviour has improved over time, therefore Todd (2005) has used 0.7 (i.e. 70 per cent) for 1990 as the proportion of heaters used carelessly.

The trend in the proportion of households achieving improved wood heater operation evident up to 2000 has slowed based on a recent national survey of wood heater use. From 2001 to 2011 a reduced rate of improved operation has been used.

The very poor operation grouping represents those heaters that regularly emit copious quantities of visible smoke. A 1999 Hobart survey, and feedback from local government officers involved in wood-smoke reduction programs in all states, suggests that about 10 per cent of chimneys/flues smoke excessively. Todd (2005) has allowed for a continuous improvement over the time series, setting 1990 at 0.2, i.e. (20 per cent) of heaters smoked excessively.

The 2007 national survey of wood heater operation and firewood parameters (Todd 2008) identified common operating behaviour that will increase particulate emissions above that found in certification testing. Specifically, 25 per cent of households blocked incoming combustion air by placing logs parallel to the fuel loading door, 17.5 per cent failed to establish a hot fire after refuelling before decreasing the combustion air, and 22.5 per cent used convection fans in ways likely to cause excessive cooling of the firebox. On the positive side 25 per cent of households always established a hot fire before reducing combustion air and 45 per cent of households did not attempt to burn their heaters overnight. The survey supported the earlier estimate that about 10 per cent of households commonly operate their heaters in a manner likely to produce excessive smoke. The survey also suggested at least half the households operated their heaters in a manner that would produce similar emissions to the certified test methods.

Open fireplaces

Emission factors

No emission testing of masonry open fireplaces has been carried out in Australia. The US (USEPA 1996) value for the particulate EF for masonry open fireplaces (17.3g/kg) has been used by Todd (2005) to derive a base CH₄ EF of 1365.8 Mg/PJ. Even though the wood species used in Australia are different from the US, this is unlikely to have a significant effect on EFs. The CSIRO tests provide particulate EF of 2.3g/kg for factory-built open fireplace (sometimes referred to as heat-recovery fireplaces). This is used by Todd (2005) to derive a base CH₄ EF of 181.6 Mg/PJ. It is assumed that the operator of an open fireplace has little impact on the emissions (on average) and so no correction factors for careless or very poor operation have been used (Todd 2005).

Proportion of open fireplaces

The proportion of open fireplaces in use is based on the same CSIRO survey and ABS surveys in 1999 and 2001 (Todd 2011).

Softwood fuel and wet wood

Emission factors

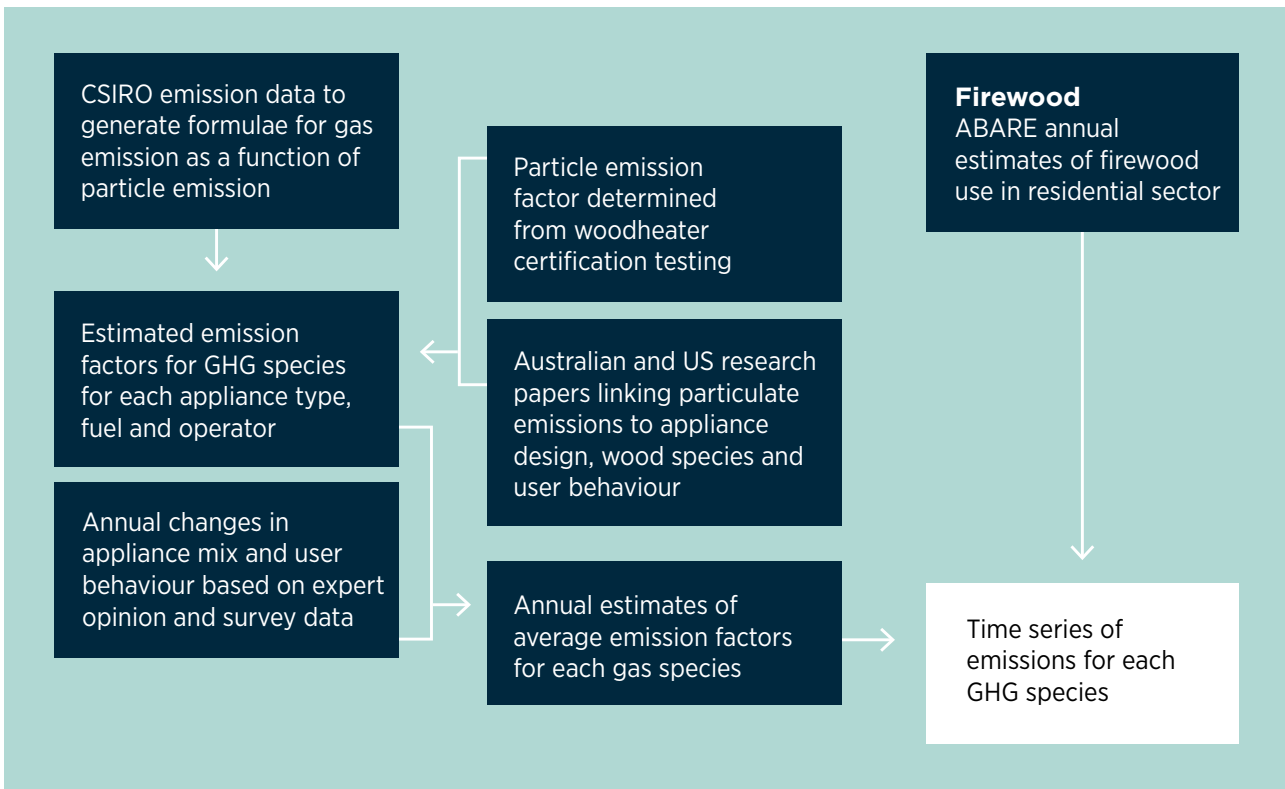

The use of wet firewood is often cited as one of the main reasons for high emissions from wood heaters. However, the CSIRO study, and other Australian studies (e.g. Todd *et al.* 1989a) have consistently shown that only very wet wood (i.e. unseasoned) influences emissions. High burn-rate tests carried out by the CSIRO have shown that very wet wood (moisture greater than 30 per cent) leads to an increase in emissions by a factor of 3.5 (Todd 2005).

The use of softwood fuel in the CSIRO testing led to a large increase in emissions (by a factor of about 3.5). However, other comparative tests of hardwood and softwood emissions (Todd 1991) have shown smaller increases. Therefore, Todd (2005) has adopted a factor of 2.

Proportion of wet wood and softwood

The 6.25 per cent proportion of households using very wet wood (>30 per cent moisture, wet weight basis) is based on a recent national survey of firewood moisture (Todd 2011). The proportion of softwood used as firewood is based on several surveys (Todd *et al.* 1989b, Driscoll *et al.* 2000, Gras 2002) that consistently show around 5 per cent of firewood consumed is softwood.

Figure 3.14 Schematic diagram of the methodology process for estimation of emissions from wood heaters

The resulting emissions factor trends are shown below in Table 3.24. With Australian standards for wood heater emissions introduced in 1992, there has been an increasing uptake of certified heaters at the expense of older, non-compliant heaters, as well as open fireplaces. Together with improving user operation, these factors work to produce an overall trend for the more complete and efficient combustion of fuelwood. This is borne out in the increasing CO₂ EF (i.e. more carbon is oxidised under improved combustion conditions) and decreasing CH₄ EF.

As a result, the implied CH₄ EF varies between 1297 Mg/PJ in 1990 and 713 Mg/PJ in 2011. This range is consistent with the 2006 IPCC defaults for residential CH₄ EFs for woodstoves (IPCC 2006, Vol. 2, Table 2.9), taking in account the inherent uncertainty of residential combustion CH₄ EFs of 50 to 150 per cent (IPCC 2006, Vol. 2, Table 2.12).

Table 3.24 Residential biomass emission factors

Inventory Year	Greenhouse Gas Emission Factor (Mg/PJ)						
	CO ₂	CH ₄	N ₂ O	CO	NO _x	NM VOC	SO ₂
1990	66.7	1,297.0	2.5	13,195.8	14.3	1,642.9	1.1
2000	75.1	844.2	2.0	9,874.9	20.3	1,069.3	1.1
2005	76.1	791.3	1.9	9,487.4	21.0	1,002.4	1.1
2010	77.3	725.9	1.9	9,007.8	21.9	919.5	1.1
Post-2010	77.5	712.7	1.9	8,910.4	22.1	902.7	1.1

Emissions from lawnmowers are estimated using tier 2 methods described by equation (3.1). CO₂ EFs are reported in Table 3.2 and non-CO₂ EFs are reported in Table 3.26. There are no fuel consumption statistics for these activities, instead allocation factors are used to derive this data from known consumption statistics. Lawn mowers are powered by small 2-stroke or 4-stroke engines and assumed to be utilised in the ratio of 60:40 (EPA NSW, 1995).

For the 1.A.4.c agriculture, forestry and fisheries category, the AES present a single total figure for diesel fuel consumed in agriculture, fisheries and forestry. However, the types of equipment used by these industries vary quite widely (tractors, log skidders, fishing boats etc.), and therefore EFs for non-CO₂ gases also vary widely. It is assumed that the agriculture, fisheries and forestry industries account respectively for 77 per cent, 6 per cent and 17 per cent of total diesel fuel consumption by the sector as a whole. This estimate is based on the relative volumes of diesel fuel for which excise rebates were claimed, as advised by the Australian Customs Service, over the period 1988 to 1994 inclusive, and have been held constant throughout the period.

These ratios were applied to EFs for the different types of diesel engines used in the types of equipment typical of the three sectors, to estimate weighted sectoral EFs (Table 3.26).

3.6.3 Uncertainties and time series consistency

The Tier 1 uncertainty analysis in Annex 2 provides estimates of uncertainty according to IPCC source category and gas.

The time series variability of GHG IEFs are likely to be influenced by changes in fuel mix within categories.

3.6.4 Source specific QA/QC

This source category is covered by the general QA/QC of the greenhouse gas inventory in Chapter 1.

3.6.5 Recalculations since the 2019 Inventory

Revisions to the Australian Energy Statistics:

Recalculations to 1.A.4 Other are detailed at the sub-category level in Table 3.27. Recalculations were largely made in response to revisions to AES.

Commercial: Natural gas has been reallocated from the Railway Transport category for the period 2009–2019. LPG and fuel oil have been recalculated for the period 2015–2019.

Residential: 2007 – 2019 has been recalculated due to revisions in petrol consumption and the inclusion of CH₄ and N₂O emissions estimates for ethanol consumption in E10 petrol.

Agriculture/fisheries/forestry: 2019 saw recalculations resulting from reductions in the amount of LPG, gasoline and diesel consumed.

3.6.6 Planned improvements

The Department will continue to look at applying revisions through to the earlier part of the time series in future Australian Energy Statistics releases and these revisions will be incorporated into future recalculations of the national inventory when available.

3.7 Source Category 1.A.5 Other (Not Specified Elsewhere)

Emissions from *1.A.5 other* are estimated using a mix of tier 1 and tier 2 approaches using EFs set out in Table 3.27.

Table 3.27 Summary of methods and emission factors: Other (Not Elsewhere Classified)

Category	CO ₂		CH ₄		N ₂ O	
	Method applied	Emission factor	Method applied	Emission factor	Method applied	Emission factor
1A5b Other (mobile)	T1	CS	T2	CS	T2	CS

Notes: T1 = tier 1, T2 = tier 2, CS= Country-specific.

3.7.1 Source category description

The source category *1.A.5 other* consists of emissions arising from fuel used in mobile equipment within defence operations.

3.7.2 Methodology

Emissions from military vehicles are estimated using tier 1 methods described by equations 3.3 and 3.4. CO₂ EFs are reported in Table 3.2 and non-CO₂ EFs are reported in Appendix Table 3.A.12.

The allocations of fuel to military transport in 2011, 2012 and 2013 are based on energy use data published by the Australian Government in accordance with the *Energy Efficiency in Government Operations (EEGO) Policy* (AGO 2007). This required the preparation of an annual whole-of-government report on the total energy use and estimated greenhouse gas emissions of Australian Government departments and agencies, and presented in the report *Energy use in the Australian Government's operations* using information reported to the Department of Resources, Energy and Tourism from all government departments and agencies – including the Department of Defence. Allocations for 1995–2007 are linearly extrapolated between the reported data points in 1994 and 2008.

This reporting has now been discontinued, and the allocations of fuel to military transport in 2014 are informed again by direct reporting of fuel consumption by the Australian Department of Defence.

The shares used to allocate fuel consumption are reported in Appendix Table 3.A.13.

3.7.3 Uncertainties and time series consistency

The tier 1 uncertainty analysis in Annex 2 provides estimates of uncertainty according to IPCC source category and gas.

3.7.4 Source specific QA/QC

This source category is covered by the general QA/QC of the greenhouse gas inventory in Chapter 1.

3.7.5 Recalculations since the 2019 Inventory

Recalculations made to 1.A.5 *other* are detailed at the sub-category level in Table 3.28.

Military Transport has had recalculations in response to revised activity data for liquid fuel consumption.

Table 3.28 1.A.5 Other: recalculation of total CO₂-e emissions (Gg), 1990–2019

3.7.6 Planned improvements

All relevant data are kept under constant review.

3.8 Source Category 1.b.1 Solid Fuels

3.8.1 Source category description

This source category covers fugitive emissions from the production, transport and handling of coal, and emissions from decommissioned mines. It does not include emissions arising from the conversion of coal into coke. Coverage of emissions for 1.B.1 Solid Fuel emission categories are shown in Table 3.29. Both methane and carbon dioxide emissions are reported under NGER for both underground and surface coal mines. Carbon dioxide, methane and nitrous oxide emissions are also reported from flaring.

In 2020, there were 38 underground mines and 73 surface mines operating nationally, while emissions are estimated for 128 decommissioned mines.

Table 3.29 1.B.1 Solid Fuels – Emissions source coverage

IPCC Category	CO ₂ emissions	CH ₄ emissions	N ₂ O Emissions

1.B.1.c Other			
Decommissioned mines		YES	
Flaring	YES	YES	YES

The great majority of Australia's resource and production of black coal are located on the east coast of Australia in New South Wales and Queensland. A very small quantity of black coal is also mined in Tasmania. In Victoria, large quantities of brown coal are mined in surface operations. A relatively small quantity of sub-bituminous coal is mined in Western Australia. The share of coal production from Australian states for 2020 is shown in Figure 3.15.

Figure 3.15 Share of coal production from Australian states – 2020

In New South Wales, the principal coal fields are the Southern, Newcastle, Hunter and the Western New South Wales Basins. In Queensland, the main coal fields are the Central Queensland, Northern Bowen Basin, the Central Bowen Basin and the Southern Basin. From 2010 to 2020, there has been strong growth in underground production from the Western New South Wales and Northern Bowen basins and declines from the Hunter and Southern Queensland basins (Figure 3.16).

Figure 3.16 Underground black coal production by coal field

There can be wide variations in both the gas content and the composition of the gas across Australian coal basins, and across coal fields within the basins. The variability and characteristics of coal gas in eastern Australia have been described by Thomson (2010) as a response to a number of distinct geological and biogenic processes, namely:

- the coalification processes;
- tectonic history;
- magmatic activity;
- groundwater flow; and
- biogenesis.

The methane in coal layers has its origins largely in the coalification process that arises from pressure and heat associated with the deep burial of biomass within sedimentary basin deposits. The burial of biomass reached a peak depth during the mid-cretaceous period when it was estimated to be around 2.5 to 4 km deep, resulting in coal layers reaching saturation with thermogenic CH₄. As gas is generated during the coalification process, coal is able to store the gas within its micropore structure. The upper limit of gas able to be held within coal follows an adsorption isotherm, which describes the pressure/temperature relationship at the point where the coal is fully saturated with gas. The isotherm is useful for representing a theoretical cap on the gas content of coal at any given depth. In the Permian coal basins of Australia's east coast, coal layers greater than 500–600 m in depth will tend to be close to saturation with thermogenic methane (Thomson 2010).

It is rare, however, for coals saturated with methane to be mined. This is because uplifting and rifting of the strata in geological periods following the coalification process provided opportunities for gas to escape through fracture systems, resulting in the upper coal layers becoming under-saturated with methane. For Australia, this started from the late Cretaceous period with New Zealand rifting away from the Australian east coast, with the associated uplifting and subsequent erosion of the coal bearing regions.

The under-saturated coal layers were then receptive to new sources of gas. Extensive magmatism activity in the Tertiary period introduced CO₂ into the upper, under-saturated coal layers. In more recent times, methanogen bearing groundwater flows through the surface fracture system have introduced biogenic methane into the upper coal layers (Thomson 2010).

A generalised model to describe the variation of gas in coal along the east coast coal bearing regions as a result of these processes has been described (Thomson 2010), and is shown in Figure 3.17. Localised geological features can also have a large influence on subsurface gas characteristics at a mine level scale. For example, faults and dykes can provide opportunities for gas to escape or be trapped and influence groundwater flows for biogenesis. In summary, the coal gas type and distribution characteristics of the eastern coalfields can be viewed as a result of the history of large scale processes overlaying localised geological features. Most near surface coal deposits on the east coast are under-saturated, as a function of their geological history. The surface zone is characterised by a very low gas content, predominantly in the form of CO₂.

Coal mining on the west coast of Australia is confined within a small coal field within the Collie basin. The Collie basin coal deposits were formed by the transport of material rather than the bed forming *in situ*. The coal beds are also commonly associated with a sandstone roof providing opportunities for gas to escape over time. The understanding of the geological characteristics, current and historical mining practices, and anecdotal evidence suggested the basin is characterised by low gas content. Mine specific emission data based on measurement is now available through NGER reporting, and is incorporated in this inventory. The data confirms that the Collie Basin coal deposits are characterised by very low gas.

Figure 3.17 Generalised model of gas variation in the subsurface for east coast Australia

Zone 1	Surface zone to ~ 100m of very low gas – CO ₂ dominant
Zone 2	Biogenic zone, 100 to 250/300m Methane increasing with depth
Zone 3	Mixed gas zone. Biogenic and thermogenic undersaturated CH ₄ Magmatic CO ₂ present
Zone 4	Thermogenic methane, increasing to saturation with depth

Source: Thomson (2010)

3.8.2 Methodology

Fugitive emissions from coal mining activities are estimated using a mix of tier 3 and tier 2 methods.

Estimates for underground mines are prepared using a tier 3 method. Data on measured CH₄ emissions for individual mines are obtained from coal mining companies reporting under NGER. For the 2020 year, data on measured CH₄ and CO₂ emissions is available for all 38 underground mines. Time series consistency has been maintained for the underground mine emissions estimates with the use of NGER data (see section 3.8.3).

Fugitive emissions from surface mining are estimated using state-specific default CH₄ emission factors, as well as incorporating facility-specific NGER data for CH₄ and CO₂ emissions, where available and appropriate.

For decommissioned mines, a country-specific tier 2 approach is used with EFs (m³ CH₄/tonne coal produced) derived from measurement data obtained for mines with similar characteristics. Flaring uses a tier 2 approach and a country-specific CO₂ EF.

Table 3.30 Summary of methods and emission factors: 1.B.1 Solid Fuels

Source Category	CO ₂		CH ₄		N ₂ O	
	Method applied	Emission factor	Method applied	Emission factor	Method applied	Emission factor

Surface mining	T3	PS	T2, T3	CS, PS	NA	NA
Post mining	NA	NA	T2	CS	NA	NA
Decommissioned mines	NA	NA	T2/T3	CS	NA	NA
Flaring	T2	CS	T2	CS	T2	CS

Notes: T2 = tier 2, T3 = tier 3, CS = Country-specific, PS = Plant-specific.

Activity data

Data on coal production provides activity data for the sector and are used as drivers for the estimation of emissions from mines in years where directly measured emissions data is not available. The production data for each mine are published annually in the statistical publications of:

- Australia – Department of Industry, Science, Energy and Resources (DISER 2022)
- New South Wales – Coal Services Pty Ltd (2019) (formerly the Joint Coal Board) and NGER data
- Queensland – Department of Resources (2020) and NGER data
- Western Australia – Department of Mines, Industry Regulation and Safety (DMIRS 2020) and NGER data
- Victoria – NGER data

Underground mining (I.B.lai)

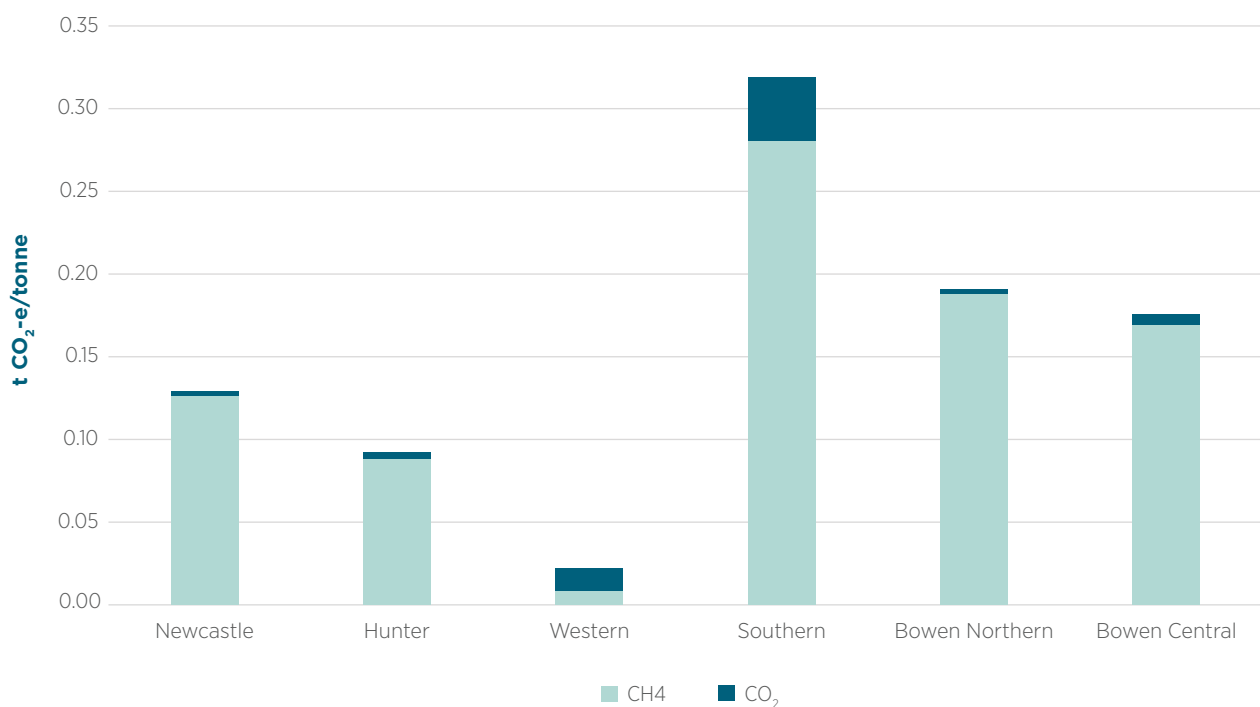

Mining activities

Emissions derived from direct measurement account for the majority of emissions from underground mines reported in the inventory. Emissions are estimated using methods set out in the *National Greenhouse and Energy Reporting (Measurement) Determination 2008* (the Determination) and are based on the measurement of gas concentration and flow within mine ventilation systems. In addition, mines are subject to state government legislation, including the *Coal Mine Health and Safety Act 2002 (NSW)*, *Coal Mine Health and Safety Regulation 2006 (NSW)*, *Coal Mining Safety and Health Act 1999 (Qld)* and the *Coal Mining Safety and Health Regulation 2001 (Qld)*, which establish mandatory monitoring regulations for mines. The Determination builds on these existing state regulatory processes.

Coal companies reporting measured CH₄ from underground mines under NGER are also required to measure and report CO₂ emissions. This is significant as, prior to NGER reporting, there was little data available on fugitive CO₂ emissions from Australian coal mining.

The NGER emission data for underground mine emissions has shown that the gas type and content of different coal fields varies significantly. This is evident in Figure 3.18, which details the average gas content profile of underground production by coal field. The gassiest coal field is the Southern New South Wales, while the least gassy field is the Western New South Wales (which is mainly CO₂).

Figure 3.18 The gas content profile of Australian underground production by coal field

Choice of emission factor

Estimates based on direct measurements were reported for all underground mines under NGER in 2020. Emissions for underground coal mines, which were closed prior to the introduction of NGER, and for which tier 3 data were not available, have been estimated by applying an average IEF for their respective coal fields.

This is consistent with the decision tree for use of facility-specific EFs, as set out in section 1.4. In applying the decision tree, it was decided that the NGER data demonstrated that facility-specific EFs, aggregated into subgroups based on spatial correlation (i.e. by coal field), were sufficiently different from the national country-specific EFs and drew on the general understanding that mines within coal fields shared common characteristics due to their shared geological history and structure. Detailed discussion as to how time series consistency has been maintained with the inclusion of NGER data for underground mines is given in section 3.8.3.

Post mining activities

Emissions from post mining activities reflect the fugitive escape of gases from the coal after mining, i.e. during preparation, transportation, storage or crushing, and are based on the measurements of Williams *et al.* (1993) and Williams *et al.* (1996). In these studies, the amount of gas retained in coal from gassy underground mines in New South Wales and Queensland, once the coal reached the surface, was analysed. Most of this gas is likely to desorb from the coal before combustion (i.e. during preparation, transportation, storage or crushing) and can therefore be classified as fugitive emissions from post mining activities. These studies related emissions E_{pm} to the quantity of black coal from underground Class A (gassy) mines QTY_a , an emission factor EF_{pm} and C_{pm} the volume-to-mass conversion factor for post mine emissions, which equals 0.6767 kg/m³.

$$E_{pm} = QTY_a \cdot EF_{pm} \cdot C_{pm} \quad (1B_1 5)$$

The emission factor, E , is the average of the results of the two empirical studies. It was found that the amount of gas retained was quite variable, but adopted an average gas EF of 1.7 m³/t raw coal, of which 75 per cent was CH₄ and 25 per cent CO₂ (Williams *et al.* 1993). An estimated factor, equal to 20 per cent of the *In situ* CH₄ content of coal (6.78 m³/tonne in this case), is applied (Williams *et al.* 1996). It is assumed that post mining emissions are associated only with black coal mined in underground gassy mines, and not with black coal mined in underground Class B (non-gassy) mines.

Surface mining (1.B.1aii)

A mix of tier 3 and country-specific tier 2 methods are used to estimate fugitive methane and carbon dioxide emissions across Australia's regional coal basins.

Table 3.31 Summary of methods and emission factors: 1.B.1 Solid Fuels: Surface mining

Notes: T2 = tier 2, T3 = tier 3, CS = Country-specific, PS = Plant-specific.

Higher tier, facility-specific, NGER method

The Department of Industry, Science, Energy and Resources has invested in a comprehensive program of measurement technique research and development since 2007 in order to underpin emissions estimation processes under NGER. An important outcome of the program has been the development of guidelines for the application of the existing NGER mine-specific (method 2/3) approach to estimating emissions from surface mines.

These guidelines have been published by the Australian Coal Association Research Program (ACARP) in December 2011, *Guidelines for the Implementation of NGER Method 2 or 3 for Open Cut Coal Mine Fugitive GHG Emissions Reporting* (C20006). These guidelines have been incorporated into a legislative instrument, the *NGER (Measurement) Determination 2008*, for the application by mines for the estimation of fugitive emissions under NGER. As indicated elsewhere, mine estimates are subject to the full audit and compliance processes that apply for other NGER Scheme reports.

Figure 3.19 Surface mines: emissions estimation process flowchart for companies

Source: ACARP 2011.

The key components of the mine-specific method for estimating emissions from surface mines (Figure 3.19) are:

- a framework for data collection, including borehole sampling and gas testing of coal and gas bearing strata, which ensures representative and unbiased sampling;
- guidelines and standards for data analysis and interpretation;
- an approach for estimating gas in near-surface zones characterised by very low gas contents;
- guidelines on utilising the collected data to produce a model of gas distribution describing the gas content and composition with a defined 3 dimensional volume. This is incorporated within the mine's 3-dimensional geological model to establish the *in situ* gas stock residing within the mine strata (e.g. geological models used for JORC Code⁹ resource evaluation, or for mine planning where JORC Code compliance is not applicable, are suitable);

9 The Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves developed by the Joint Ore Reserves Committee (JORC).

- guidelines on estimating the emissions released from the *in situ* gas stock as blocks of strata within the mine are extracted for coal production; and
- minimum qualifications of persons who are permitted to estimate emissions from an surface mine using the higher order method.

The *NGER (Measurement) Determination 2008* sets out requirements for the sampling and analysis to be undertaken by facilities to determine the gas content contained in rock strata within a coal mine; the parameters for the low gas zone, and the application of a gas distribution model to develop an emissions estimate for a surface mine as well as the determination of a low gas zone.

A description of the conceptual framework supporting the facility-specific NGERS method is detailed below.

A. For estimating total surface mine fugitive emissions in a year:

$$E_j = \gamma_j \sum_z (S_{j,z})$$

Where E_j is the fugitive emissions of gas type (j) that result from the extraction of coal from the mine during the year (CO₂-e tonnes)

γ_j is the factor for converting a quantity of gas type (j) from cubic metres at standard conditions of pressure and temperature to CO₂-e tonnes, as follows:

- (a) for methane— $6.784 \times 10^{-4} \times 25$
- (b) for carbon dioxide— 1.861×10^{-3}

$\sum_z (S_{j,z})$ is the total of gas type (j) in all gas bearing strata (z) under the extraction area of the mine during the year, in cubic metres

B. For estimating the total gas contained by gas bearing strata for (A) above:

1. For $S_{j,z}$ for gas type (j) contained in a gas bearing strata (z) under the extraction area of the mine during the year, in cubic metres, is:

$$S_{j,z} = M_z \times \gamma_z \times GC_{jz} - \sum_t Q_{ij, \text{cap}, z} - \sum_t Q_{ij, \text{flared}, z} - \sum_t Q_{ij, \text{itr}} - \sum_t E_{j, \text{vented}, z}$$

- Where M_z is the mass of the gas bearing strata under the extraction area of the mine during the year, in tonnes
- γ_z is the proportion of the gas content of the gas bearing strata that is released by extracting coal from the extraction area of the mine during the year, as follows:
- (a) if the gas bearing strata is at or above the pit floor-1
 - (b) for gas released below the pit floor
- GC_{jz} is the content of gas type (j) contained by the gas bearing strata (z) before gas capture, flaring or venting is undertaken at the extraction area of the mine during the year, measured in cubic metres per tonne of gas bearing strata at standard conditions
- $\sum Q_{ij, \text{cap}, z}$ is the total quantity of gas type (j) in coal mine waste gas (i) captured for combustion from the gas bearing strata at any time before coal is extracted from the extraction area of the mine during the year, in cubic metres
- $\sum Q_{ij, \text{flared}, z}$ is the total quantity of gas type (j) in coal mine waste gas (i) flared from the gas bearing strata (z) at any time before coal is extracted from the extraction area of the mine during the year, in cubic metres
- $\sum Q_{ij, \text{itr}}$ is the total quantity of gas type (j) in coal mine waste gas (i) transferred out of the mining activities at any time before coal is extracted from the extraction area of the mine during the year, in cubic metres
- $\sum E_{j, \text{vented}, z}$ is the total emissions of gas type (j) vented from the gas bearing strata (z) at any time before coal is extracted from the extraction area of the mine during the year, in cubic metres
2. In subsection (1), $\sum Q_{ij, \text{itr}}$ applies to carbon dioxide only if the carbon dioxide is captured for permanent storage
 3. For GC_{jz} in subsection (1), the content of gas type (j) contained by the gas bearing strata (z) – see C below

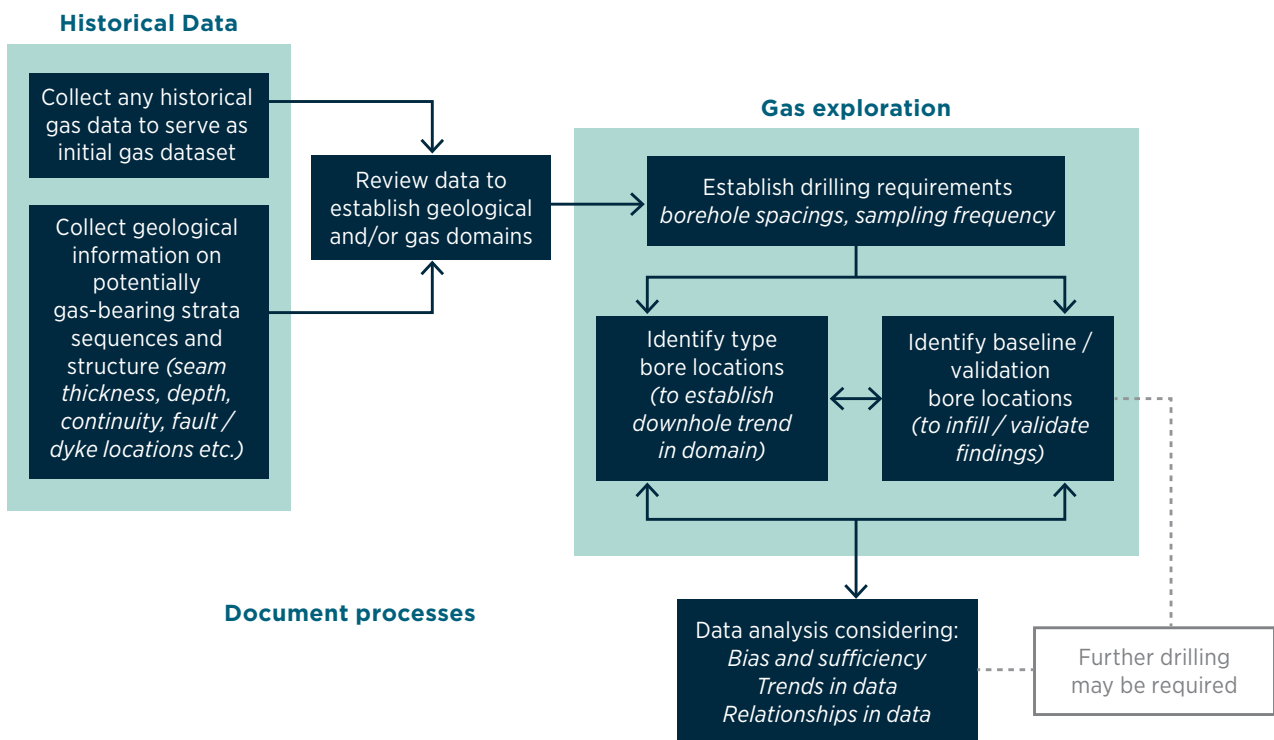

C. For estimating the content of gas type (j) contained by the gas bearing strata (z) total gas contained by gas bearing strata for (B) above:

Data collection and gas testing

A minimum of 3 boreholes that capture the full variance of the gas trends with depth must be located within each gas domain (i.e. area of common gas characteristics). Assessment of the requirement for any additional boreholes is carried out via an iterative process of data review during the gas exploration process to ensure that a sufficient number of unbiased samples have been collected (Figure 3.20).

Sample selection involves the collection of core samples that are representative of the strata that their results will be characterising, and to limit any air contamination both in the field and in the laboratory. Gas testing involves the measurement of each sample’s gas content (desorption) and composition according to the Australian Standard AS3980-1999.

The low gas zone

In most mine sites, there is a portion of strata immediately below the surface that is lacking in quantifiable quantities of coal seam gases. Gas properties in strata with no or low gas volumes are difficult to measure accurately due to inherent uncertainties associated with sampling and testing processes.

A gas dataset of over 2,000 samples from New South Wales and Queensland were analysed to provide an alternative method for the estimation of emissions from low gas zones in the subsurface. It was found that there is a 'low' or 'no' gas zone present at most surface coal mines from surface down to a clearly apparent boundary at varying depths. There is a key set of common characteristics observed in these low gas zones:

- over 95 per cent of samples reported gas contents under 0.5 m³/t;
- over 95 per cent of samples are commonly carbon dioxide (CO₂) and nitrogen (N₂) in gas composition;
- at the horizon where the gas contents increase to over 0.5 m³/t, the gas compositions simultaneously switch to close to 100 per cent methane (CH₄); and
- this horizon is closely related to the 2 main weathering profiles at the deposit:
 - base of oxidation or water table horizon, and
 - base of weathering (or fresh rock horizon).

Samples within the low gas zone are assigned a default emissions factor. Therefore, all gas bearing strata (i.e. coal and carbonaceous strata with a density less than 1.95 g/cm³) are assigned the default value, obtained from half the measurable quantities of both components observed in this zone: i.e. 0.25 m³/t at 50 per cent CO₂ gas composition.

Process used for inclusion of NGER surface mine emission data into the national inventory

NGER emissions for surface mines have been incorporated into the national inventory, having regard to the following procedures and issues:

- Consistency with the IPCC guidelines and comparison with international practice;
- Previous ERT report comments – that have both recommended and encouraged Australia to incorporate NGERs emission data for surface mines, when available, into the National Inventory; and
- Inventory quality control procedures for data:
 - NGER data has been subject to quality control procedures specific to inventory purposes, consistent with the national inventory Quality Assurance/Quality Control Plan, as set out in section 1.6 of the NIR.
 - A decision making process with respect to the use of facility specific EFs is set out in section 1.4.1.

The major issue for which the inventory compilation process must control relates to the question of whether the sample of mines that have estimated emissions using the higher tier methods contains a sampling bias and is not representative of the entire population of coal mines in Australia. At this stage, there is insufficient evidence to indicate that this is the case. This is due to the differing characteristics of individual coal fields, and because companies may select between Method 1 and Method 2/3 when estimating emissions under NGERs. Some mines have not estimated emissions using the higher tier methods (non-reporting mines).

Consequently, the reported facility-specific emissions data has been divided into subgroups based on individual coal basins or coalfields with the use of data and approaches to the treatment of non-reported data set out as below.

In Queensland basins, other than Surat, the number of NGER reporters reporting facility-specific emission estimates using higher order NGER methods is considered to be not sufficient for the sample to be representative of the sub-population of the coal basin. In these cases, the facility-specific NGER emission factors for reporting mines may be incorporated into the inventory but the tail of non-estimating mines is constrained such that the total IEF for the coal field is equal to the pre-existing country-specific emission factors. This means that total emissions for these coal fields are not affected by the inclusion of facility-specific data, for this submission.

In the Western, Surat and Collie coal fields – where previously there has been no empirical data available, the number of reporting mines under NGER is much higher and is considered to be sufficiently representative to be included in the inventory. In these cases, facility-specific NGER data have been incorporated into the inventory but the emission factors of these reporting mines have, conservatively, not been extrapolated to the non-reporting mines. In the absence of any pre-existing empirical data for these coal fields the pre-existing country-specific emission factors have been used for the tail of non-estimating mines.

In the case of the Gunnedah Basin, the near universal reporting of higher tier facility data has demonstrated the basin to be significantly different from the existing tier 2 country-specific methane emission factor. Therefore, in this case, a Gunnedah Basin-specific methane emission factor has been developed from facility NGER data and applied to mines in the Gunnedah Basin mine for which high tier methane data are not available.

In practice, the use of facility-specific data have been implemented for the Gunnedah, Western, Surat, Collie, Hunter and Newcastle coal fields. The remaining coal fields in Queensland do not use NGER reported data and retain the use of existing tier 2 country-specific methods (see below).

Black coal mine production

A study of methane flux measurements from surface coal mines in New South Wales (Williams *et al.* 1993) and a database of in-situ measurements from Queensland gas seams (Department of Natural Resources and Mines, 2016) forms the basis for Australia's country-specific, default emission factors. The study used the empirical results to estimate EFs (in m³/tonne raw coal) applicable to surface black coal mining, as shown in Table 3.32.

Brown coal (lignite) mine production

Surface mining of brown coal (lignite) occurs in Victoria for combustion in electricity generation. A methane emission factor for Victorian brown coal mining of 0.0162 m³ per tonne of raw coal mined is applied. The emission factor is based on a gas measurement program conducted in 2013, which consisted of 96 samples taken from six boreholes across three brown coal mining deposits (HRL 2013).

Surface mining of a low rank sub-bituminous coal occurs in South Australia for combustion in electricity generation. Coal mined in South Australia has an energy content of 13.5 GJ/t. Based on the IEA fuel type classification, which classes non-agglomerating coals under 17.435 GJ/t as being lignite (IEA 2005), the methane EF from surface brown coal mining of 0.0162 m³/t (as used for Victorian brown coal) has been applied.

Table 3.32 Tier 2 default CH₄ emission factors for surface mining

State	EF CH ₄ m ³ /t raw coal mined	Volume-to-mass conversion factor ^d kg/m ³
NSW	3.2 ^(a)	0.6767
Bowen (Qld)	1.65 ^(a)	0.6767
Tasmania	1.0 ^(c)	0.6767
South Australia	0.0162 ^(f)	0.6767
Victoria	0.0162 ^(f)	0.6767

Decommissioned mine emissions (1.B.1.C Other)

Methane emissions are also known to occur under certain conditions following closure of coal mines. Leakage into the atmosphere through fractured rock strata, open vents and seals occurs over daily to decadal timescales.

The Australian methodology is based on the approach developed in the 2006 *IPCC Guidelines for National Greenhouse Gas Inventories*. The decline of emissions following mine closure are modelled using emission decay curves (EDCs) for dry gassy and non-gassy mines. In addition, the EDCs are adjusted on a mine-by-mine basis, according to the flooding characteristics of each mine.

Key data required for the approach include:

- mine closure history;
- emissions at time of closure;
- dry mine EDCs for gassy and non-gassy Australian mines;
- mine void size; and
- mine water inflow rates.

The approach seeks to maximise the use of publicly available data and is best described as a high tier 2 and tier 3 approach. It is consistent with a tier 3 approach in that it estimates emissions on an individual mine basis. However, other mine-specific data characteristic of higher level tier 3 approach are absent, such as characteristics of the mined coal seam, permeability and direct measured emissions.

The EDC methodology used for estimating CH₄ emissions from decommissioned mines can be described as:

$$E_{dm} = (E_{tdm} \cdot EF_{dm} \cdot (1 - F_{dm})) - E_{rec} \quad (1B_1-7)$$

Where E_{dm} is the emissions (Gg methane/year) for a mine at a particular point in time

E_{tdm} is the annual emission rate of the mine at point of decommissioning (Gg methane/year)

EF_{dm} is the emission factor for a mine at a point in time since decommissioning. It is derived from the EDC (formulae 1 B1_8 and _9). The EF is dimensionless

F_{dm} is the fraction of mine flooded at a point in time since decommissioning E_{rec} is the quantity of methane emissions avoided by recovery

Emission Decay Curves (EDCs)

An EDC describes the decline in fugitive CH₄ emissions over time following mine closure. Hyperbolic curves have been found to function best in portraying the rapid decline in emissions in first few years, followed by a slow decline over time of the remaining emissions.

Australian-specific EDCs were utilised for gassy and non-gassy mines respectively. The EDCs represent the dry mine case and have been developed from studies of long term (1982-2006) direct gas emission measurements from Australian mines (Lunarzewski 2005 and Armstrong *et al.* 2006). The EDCs are shown in Figure 3.21, and are described in the following formulae:

Gassy mines

$$EF_{dm} = (1 + A * T)^b - C \quad (1B_8)$$

Non-gassy mines

$$EF_{dm} = (1 + A * T)^b - C \quad (1B_9)$$

Where EF_{dm} is the emission factor (Gg methane/year) for a mine at any point in time since decommissioning (the emission factor is dimensionless)

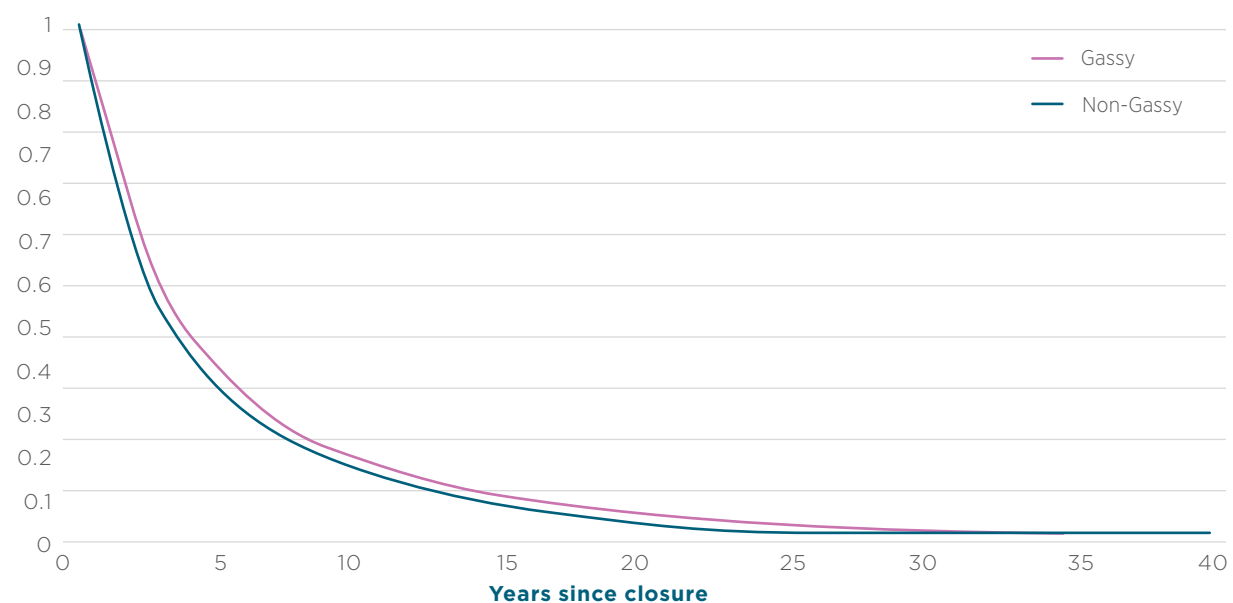

T is the time (years) elapsed since decommissioning of mine

A, b and C are coefficients unique to the decline curves (see Table 3.33)

Table 3.33 Coefficients used in Australian emission decay curves from decommissioned mines

Mine category	Coefficients		
	A	B	C
Gassy Mines	0.23	-1.45	0.0242
Non-Gassy mines	0.35	-1.01	0.0881

Figure 3.21 Emission decay curves for gassy and non-gassy Australian decommissioned coal mines

Source: Lunarzewski 2005 and Armstrong *et al.* 2006.

Mine Production Data

Mine production data are obtained from:

- NGER Scheme for mines from 2009 to 2020
- Coal Services Pty Ltd (2020), for New South Wales mines from 1972 to 2020; and
- Department of Resources (2020) for Queensland mines from 1979 to 2020.

In both datasets, details were obtained for mine type (underground/surface), annual run-of-mine production, and time of closure. Only underground mines were included in the study. Surface mines were not included in the study as they are associated with relatively low CH₄ emissions. This approach is consistent with that presented in the 2006 *IPCC Guidelines for National Greenhouse Gas Inventories*.

Emissions at Closure

In order to estimate the decline of emissions over time following closure, it is first necessary to establish emissions at year zero, i.e. emissions at the point prior to closure. The approach used is consistent with that used to estimate CH₄ emissions from active underground coal mines (see 1.B.1ai). Final mine production at closure is taken as the last full year of production.

Decommissioned mines are defined as Class A (gassy) or Class B (non-gassy) based on existing classifications used to calculate previous *National Greenhouse Gas Inventories*. For earlier mines, for which class tends to be unknown, mines were classified according to their geological proximity to other mines for which class was known.

Adjustment of EDC for flooding mines

It is common for decommissioned mines to become flooded over time. The flooding of mines is known to result in a very rapid decline in the release of CH₄, thus having a substantial impact on the shape of the EDC, and on overall emissions.

The approach uses emission values calculated using dry mine EDCs (formulae 1B1_8 and 1B1_9) and makes adjustments based on the proportion of the mine flooded at that time. For example, if a mine is 50 per cent flooded 10 years post closure then the emission value derived from the EDC is adjusted at that point in time by 50 per cent.

The following information is required in order to estimate the flooding rate of any particular mine:

- size of the mine void volume; and
- rates of mine water inflow.

Estimating mine void volume

The quantity of run-of-mine coal production removed from the mine is used as a basis for estimating the mine void volume remaining at the time of closure. Total historical mine run-of-mine coal production is converted from tonnes to cubic metres by dividing the total tonnage by 1.425, representing the specific gravity of an average Australian worked coal seam Lunarzewski (2006).

Mine water production data are difficult to obtain on a mine by mine basis, particularly for older, decommissioned mines. The approach taken is to develop a set of basin/state average mine water inflow rates based on available data.

The primary source of mine water production rates for individual mines were obtained from publicly available Environmental Impact Statements (EIS) for mining development projects. EIS provides a good coverage of groundwater hydrology, providing data on mine water production rates for proposed mines, extensions, nearby existing mines, and the flooding status of surrounding mines.

Water production rates for three regions were calculated using these data sources. The Southern New South Wales region contained mine water production rates ranging between 1 – 5.0 ML/Day and an average value of 2.5 ML/Day. The Central New South Wales region ranged between 0.4 and 3 ML/Day and an average value of 1.2 ML/Day and Queensland ranged between 0.1 and 0.4 ML/Day and an average value of 0.2 ML/Day.

The following assumptions were necessary in estimating mine water inflow rates:

- the mine floods at a linear rate;
- mine water production is the same for each mine on a basin/state scale; and
- CH₄ is produced evenly throughout the mine and flooding reduces the emissions proportionately to the void volume flooded.

Fully Flooded Mine Emissions

Once a mined void area has been fully flooded, the associated primary gas sources can no longer release gas into the workings. However, remaining free gas in the strata and desorbing gas from unflooded secondary gas sources could continue to leak into the atmosphere (ground surface) via fractured rock strata i.e. geological faults, cracks, and fissures (structurally induced pathways). A constant of 2 per cent of the emissions at the time of mine closure has been adopted to represent emissions once fully flooded (Lunarzewski 2006).

Mine flaring emissions (I.B.I.c. Other)

Data for 2009 to 2020 on the recovery and flaring of CH₄ from coal mines is available from mines reporting under the NGER Scheme. Time series consistency for coal mine flaring is maintained by the inclusion of flaring data obtained from a 2006 unpublished report on coal mine methane prepared for the Australian Greenhouse Office (AGO 2006b), which provided flared gas quantities by mine for 2005.

For those respective mines, the 2005 flared quantity was then prorated according to the total mine methane emissions for other years to produce a time series. Information regarding when flaring systems were first installed at the respective mines were also taken in to account in producing the time series.

The mine flaring emissions have been reported under *I.B.I.c. Other – Flaring*. Although the Solid Fuel CRF Table 1.B.1 does not facilitate the reporting of N₂O emissions from flaring, the UNFCCC reporting tool does allow reporting, and the inclusion of N₂O is evident under Solid Fuels in the CRF Summary Table 2.

The emission estimation methodology utilises a default combustion CO₂ EF of 51.9 Gg/PJ and an energy content of 37.7 GJ/m³ for coal mine waste gas flared, derived from industry data. Facility CO₂ EFs are utilised from NGER data where available. A flaring efficiency factor of 98 per cent is used, consistent with the IPCC *Good Practice Guidance 2000* and *2006 IPCC Guidelines*.

3.8.3 Uncertainties and time series consistency

The tier 1 uncertainty analysis in Annex 2 provides estimates of uncertainty according to IPCC source category and gas.

Underground Mines

NGER data is used for inventory years from 2009 to 2020. The transition from industry surveys and company to NGER data for underground coal mines is carefully managed to ensure that time series consistency has been respected. It is *Good Practice* to perform the splicing using more than one technique before making a final decision and to document why a particular method was chosen. The surrogate method, involving the use of coal production data and an EF derived from actual mine measurements, was chosen as the most appropriate splicing technique. This choice was made because run-of-mine coal production data is available for individual mines for all years and is an underlying activity data parameter that best explains emission trends.

Interpolation was considered as a complementary approach where emissions data are available from non-NGER sources for a previous year and which could be used to provide an EF per unit of coal production for earlier years. In accordance with *Good Practice Guidance* (IPCC 2000), interpolated estimates were compared with surrogate data as a QA/QC check.

For years before NGER data became available, data on emissions for certain underground mines was available from estimates published within company environmental reports or from industry reports to the Australian Greenhouse Office (AGO 2006b). This emissions data has been used for each mine for the years for which they are available.

For earlier years, where such emissions data are not available, an EF per unit of production for each mine was established and applied to production levels back through the time series from 1990 to the year when data on emissions first becomes available. For the years between the latest company report and the year of the NGER data, the EF for each mine was calculated by interpolating between the EF for the latest year for which company data was available and the EF based on NGER data for the year 2009.

A small number of underground mines closed in the period 1990–2005 for which there are no mine-specific measured data available. Emissions for each year were recalculated using a basin-specific factored, calculated from the NGER data for 2009 and multiplied by production. A similar approach has been adopted for the inclusion of emissions of CO₂ for all mines (Table 3.34 and 3.35).

Table 3.34 Time series consistency method for determining underground coal mine emission factors – CH₄

Methane	1990–2004	2005 Industry survey	2006–2008	2009–19 NGER	2020 NGER
<p>“Actual” data reported EFs held by companies represents constant the best available and most representative for the year – back cast based on latest available year of actual data.</p> <p>Basin specific factors (based on NGER data) used for mines for which NGER data was not available</p>	Actual data	Actual data	Interpolated EFs	Actual data	NGER data backcast only until an actual emissions data year is available using interpolation to fill intervening years.

Table 3.35 Time series consistency method for determining underground coal mine emission factors – CO₂

Carbon dioxide	1990–2008	2009–19 NGER	2020 NGER
Basin specific factors (based on NGER data) used for mines for which NGER data was not available.	EFs held constant	Actual data	Emissions for all earlier years are estimated using the production EF based on mine-specific NGER data.

Surface mines

NGER data is used for inventory years from 2009 to 2020. The transition to NGER data for surface coal mines in this inventory submission is undertaken in a manner that maintains time series consistency. A set of rules has been applied that takes into account the new understanding of gas content gained from NGER data and maintains the relevance of the original 1993 study for mines and basins where measurements were previously undertaken.

Where the NGER data is an improvement on the country-specific Tier 2 EF because coal fields are outside the area of the original study (Gunnedah, Western, Surat coal fields), then the earliest NGER Scheme facility-specific EF has been applied through the entire time series. Where the new data improves on the old EF because comprehensive NGER Scheme measurement provides updated and improved data of the original study area measured in 1993 (Hunter and Newcastle) then, for methane, the earliest NGER Scheme facility-specific EF back through the time series by interpolating back until year of original study (1993) or, if mine was not part of original study, then the NGER derived factor is applied to the entire time series.

For carbon dioxide, where no measurements previously exist, then the earliest NGER facility-specific EF is applied to the entire time series.

3.8.4 Source specific QA/QC

This source category is covered by the general QA/QC of the greenhouse gas inventory in Chapter 1.

Implied emission factors

International comparability

The Department of Industry, Science, Energy and Resources undertook analysis of methane implied emission factors (IEFs) for Australian coal mines to compare statistically with the IEFs reported by other countries in accordance with the Quality Assurance-Quality Control Plan. Overall, it was found that Australia's IEFs for methane emissions were not significantly different to the means of the 2019 IEFs of all other reporting parties (Figure 3.22 and 3.23). The 2019 data from other reporting parties was used for comparison purposes because 2020 data from key coal producing parties were not available at the time.

Figure 3.22 Implied emission factor (IEF) for methane from solid fuel underground mine (kg/t) for Annex I countries (2019) and IEF for Australia (2020)

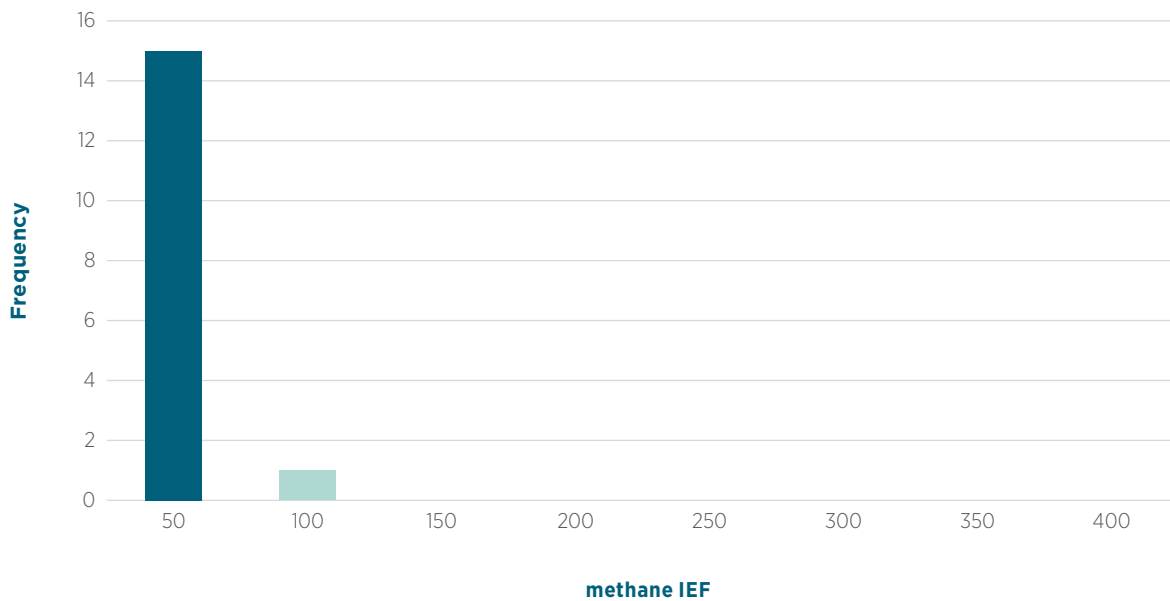

Figure 3.23 Implied emission factor (IEF) for methane from solid fuel surface mines (kg/t) for Annex I countries (2019) and IEF for Australia (2020)

In 2020, Australia's IEF for methane from underground mines was 5.68 kg CH₄/t compared with 69.13 kg CH₄/t (n =17) for the 2019 mean of all countries. The result of a t-test comparison of the means showed that the methane IEF from underground mining in Australia is not significantly different to that of the mean IEF for all reporting countries.

Australia's IEF for methane from surface mining in 2020 was 0.66 kg CH₄/t compared to 0.66 CH₄/t (n = 17) for the 2019 mean of countries. The result of a t-test comparison of the means showed that methane IEF from surface mining in Australia is not significantly different to that of the IEF mean for all reporting.

The IEF for carbon dioxide emissions from underground mining in 2020 was 10.95 kg CO₂/t. Statistical comparison with other countries was not possible as very few countries report CO₂ emissions from coal mining. However, the figure is comparable to levels of carbon dioxide associated with underground mines in Russia. A study of 16 mines in the Kuznetskiy and Pechorskiy coal basins by Ruban *et al.* (2006) found 11.4 kg CO₂ per tonne of coal produced.

Time series consistency – trends in implied emission factors

Estimates are tested for time-series consistency in accordance with the Quality Assurance – Quality Control Plan. The IEFs from total coal mining activities for Australia are influenced over time by changes in the share of production from mines of varying gas content and gas type and the quantity of methane recovered. This is evident in a declining trend of the methane IEF for underground mines, which reflects a relative increase in production from less gassy mine regions compared to production from high gas coalfields. Figure 3.24 details the declining trend of the underground coal mine IEF since 1990 and the corresponding fall in production from the New South Wales Southern Coalfield, which has the highest IEF of Australian coalfields. In more recent years the increasing use of flaring to combust methane that otherwise would have been vented has acted to reduce the IEF for underground mines in total.

The IEF for all coal mining activities has also declined since 1990 reflecting the additional influence of a relative increase of surface mine production compared to underground production. The trend in production also varies over time, reflecting the effects of opening and closure of large mines, commodity prices and global demand.

The IEF for surface mines also exhibits a decline over time reflecting changes in the relative weight of production from gassy to non-gassy mines between 1990 and 2020.

Figure 3.24 Decline of the overall underground coal mine methane implied emission factor compared with the fall in production from the high gas content Southern Coalfield

Measurement audits

The NGER Scheme facility-specific method for surface mines involves extensive measurement of in-situ gas within each respective coal mine's coal and carbonaceous rock strata, via borehole drilling and sampling.

All measurements used to support facility-specific estimates of emissions are subject to at least three controls.

First, the NGER legislation sets out minimum qualifications of the estimator of surface mine emissions using the NGER Scheme higher tier method. The Estimator is a person, or team of persons, meeting the minimum qualifications described below, who estimates the fugitive emissions from a surface coal mine.

The minimum qualifications of an Estimator are 5 years experience in the assessment of coal deposit continuity and dimensions including the identification of geological features that affect coal seam geometry such as seam splitting, subcrop lines, washouts, and otherwise deterioration in thickness of the coal seams, including (but not limited to) the presence of any adverse structural features (for example faults, folds or igneous intrusions).

Second for NGER data submitted during the operation of the carbon pricing mechanism (2012-2015), companies that had an annual emissions that exceeded 125 000 Gg CO₂-e were required to undertake a pre-submission audit report to provide assurance over their NGER Scheme emissions report. Audit reports had to have been submitted to the Clean Energy Regulator by the reporting due date of 31 October. The audit had to have been a reasonable assurance engagement, it must have been conducted in accordance with the *National Greenhouse and Energy (Audit) Determination 2009*, and it must have been undertaken by a Category 2 or 3 registered greenhouse and energy auditor.

Third, the Clean Energy Regulator is empowered under the *National Greenhouse and Energy Reporting Act 2007* to investigate any emission estimates at any time and has a program to undertake a risk-based audit process to provide assurance on the quality of data reported under the NGER Scheme.

Use of NGER Scheme facility level data in the national inventory

The use of NGER data addresses comments made in previous ERT reports which have both recommended and encouraged Australia to incorporate NGER data for surface mines.

Nonetheless, the application of NGER Scheme facility data must be undertaken with care to ensure that issues of selection bias are controlled for. In order to manage these risks, the Department has aggregated the available data into a national account in accordance with principles established in the 2006 IPCC Guidelines and elaborated at the IPCC workshop on the use of facility level data held in Sydney, August 2010 (and as explained in Chapter 1).

In the case of surface mines, not all facilities have undertaken facility specific measurements. In Queensland, apart from the Surat Basin, insufficient facility-specific estimates have been obtained and, in the absence of a sufficient sample of data, the national inventory continues to apply default values for emission factors for coal basins in Queensland (other than the Surat Basin). The cost of measurement of emissions is significant and, as a result, would have ensured that companies were reluctant to undertake measurements. It is not clear, consequently, that the default value used to estimate emissions from Queensland is not an unbiased estimate of emissions.

While the effect of selection bias remains possible for Queensland coal basins other than the Surat Basin, this small risk has been mitigated through the country-specific value – 1.65 CH₄ m³/t raw coal mined – which is within the range of IPCC default values available. This country-specific value has been recently updated and is described in the following section.

Review of brown coal (lignite) surface mining emission factor

Australia undertook an independent technical review of the new emission factor prior to adoption for inventory reporting. The review found conformity with IPCC guidelines and consistency with other comparable international greenhouse gas inventories. It found the emission factor constituted best practice for estimating emissions from surface coal mining (Pitt and Sherry 2015).

3.8.5 Recalculations since the 2019 Inventory

Since the submission of the 2019 inventory, there were minor revisions to activity data from NGER for 2019 inventory years for underground and surface mines. The Department also made a change to the Tier 2 emissions factor for Queensland surface mines, primarily impacting mines located in the Bowen Basin. Recalculations are shown in Table 3.37.

Update to Queensland Tier 2 surface emissions factor

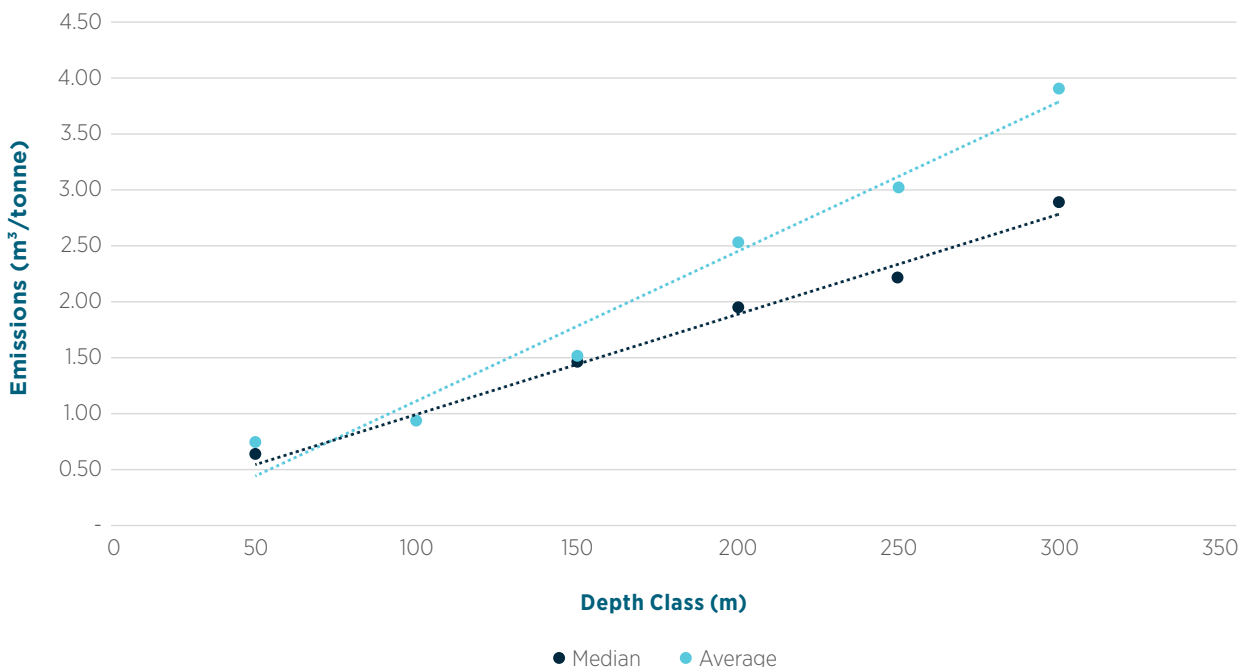

The emergence of the satellite data-based analysis of methane emissions, which included a region in Queensland (QLD), prompted the Department to review its existing methods for the estimation of methane emissions from QLD surface coal mines, implemented from this submission.

The estimation of methane emissions from underground coal mines is considered reliable coming, as it does, from monitors located in mine shafts operating under State Government OH&S requirements and reported to the Clean Energy Regulator under the NGER Scheme. However, the method for surface coal mines relies on data on the size of the coal operations and emission factors derived from Commonwealth Scientific and Industrial Research Organisation (CSIRO) research. These emissions factors were derived from a 1993 study which measured methane fluxes in a small number of locations in the Bowen Basin.

The improved method is based on data on the methane content in coal seams in the Bowen and Surat Basins, derived from the QLD Government Petroleum Exploration Dataset (the Petroleum dataset). The Petroleum dataset includes geological data sourced from drilling of petroleum wells, coal seam gas wells (CSG), stratigraphic bores, coal and mineral drill holes. Measurements from the Petroleum dataset provide an estimate of methane in the coal seams waiting for release (a 'bottom-up' estimate of methane emissions from surface coal mines), with the new method presuming that all gas contained within the coal seam will be released upon the coal's extraction.

The Petroleum dataset was processed to exclude gas content data outside active coal mine fields and aggregate the drill hole observations into 50m depth classes by average and median values. The results of the pre-processing demonstrated a strong, linear relationship between the methane content of the strata and the depth class at which the measurement was taken (Figure 3.25).

Figure 3.25 Methane content by depth of measurement

The average values in Figure 3.25 are higher than the median due to the presence of outlier observations in wells/drill holes with significantly higher gas contents. These outlier observations were retained as it is not uncommon within the fugitive emissions category for a small amount of locations to emit a higher proportion of total emissions.

A desk top analysis of coal mining environmental and planning documents was conducted to determine common operating depths of QLD surface coal mines and expert judgement was applied to determine what proportion of mining activity occurred within a specific 50 m depth class. This analysis was then used to derive the emissions factor using the average methane content values in Figure 3.25, as set out in Table 3.36.

Table 3.36 Comparison of previous and improved CH₄ emission factors for surface coal mines

Emissions factor (CH ₄ m ³ /tonne of coal prod)	
Improved method	1.65
Previous method	1.20

The result of the improved method is an increase in emissions across the time series (Figure 3.26.). The average annual increase in fugitive emissions for QLD surface coal mines is 1.6 Mt CO₂-e. The method improvement increases annual emissions from the fugitive emissions from fuels and total inventory by an average of 3.6 per cent and 0.3 per cent respectively (1.6 Mt CO₂-e) across the time-series between 1990 and 2021.

Figure 3.26 Fugitive emissions estimates for QLD surface coal mines

These revisions represent a significant improvement in the method for estimating emissions from QLD surface mines. The Petroleum dataset underpinning the revised emissions factor has greater geographic coverage and a much larger number of observations than the original CSIRO study, decreasing uncertainty and the influence of natural variability.

Table 3.37 1.B.1 Solid Fuels: recalculation of total CO₂-e emissions (Gg), 1990–2019

	2021 submission	2022 submission	Change	
	(Gg CO ₂ -e)	(Gg CO ₂ -e)	(Gg CO ₂ -e)	(per cent)

3.8.6 Planned improvements

Uptake of the higher tier method is expected to continue over future years as new mining areas are opened up, resulting in an increase in mine-specific emission data available for compiling surface mine emissions for the inventory. The Department will continue to investigate options for determining mining depth of individual mines to enable the development of facility-specific emissions factors which takes into account that facility's mining practices, enabling a Tier 3 approach for estimating emissions from Australian surface coal mines. The Department will also investigate opportunities to apply the improved QLD method to other jurisdictions, where sufficient geological data is available.

The Department is planning to undertake the development of a methodology for estimating emissions from coal exploration boreholes. The method will aim to incorporate country-specific data where possible.

3.9 Source Category 1.B.2 Oil and Natural Gas

3.9.1 Source category description

The IPCC *Guidelines* defines a three level hierarchical structure for source categories related to the oil and gas industries. At the top level of the hierarchy is:

- emissions related to oil (1B2a);
- emissions relating to gas (1B2b); and
- venting and flaring emissions relating to both oil and gas (1B2c).

The 2006 IPCC Guidelines reference the American Petroleum Institute's (API) 2009 *Compendium of Greenhouse Gas Emissions Methodologies for the Oil and Gas Industry definitions*:

- vents are emissions that are the result of process or equipment design or operational practices; and
- leaks are emissions from the unintentional equipment leaks from valves, flanges, pump seals, compressor seals, relief valves, sampling connections, process drains, open-ended lines, casing, tanks, and other leakage sources from pressurised equipment not defined as a vent.

Fugitive emissions associated with various segments of the coal seam gas production chain are reported consistent with UNFCCC reporting requirements, inclusive with emissions from natural gas under *1.B.2.b.1 natural gas exploration, 1.B.2.b.2 natural gas production, 1.B.2.b.3 natural gas processing, and 1.B.2.c venting and flaring*.

Fugitive emissions associated with the transportation of coal seam gas are reported, inclusive with emissions from natural gas, under the national inventory reporting source categories of *1.B.2.b.4 natural gas transmission/storage and 1.B.2.b.5 natural gas distribution*.

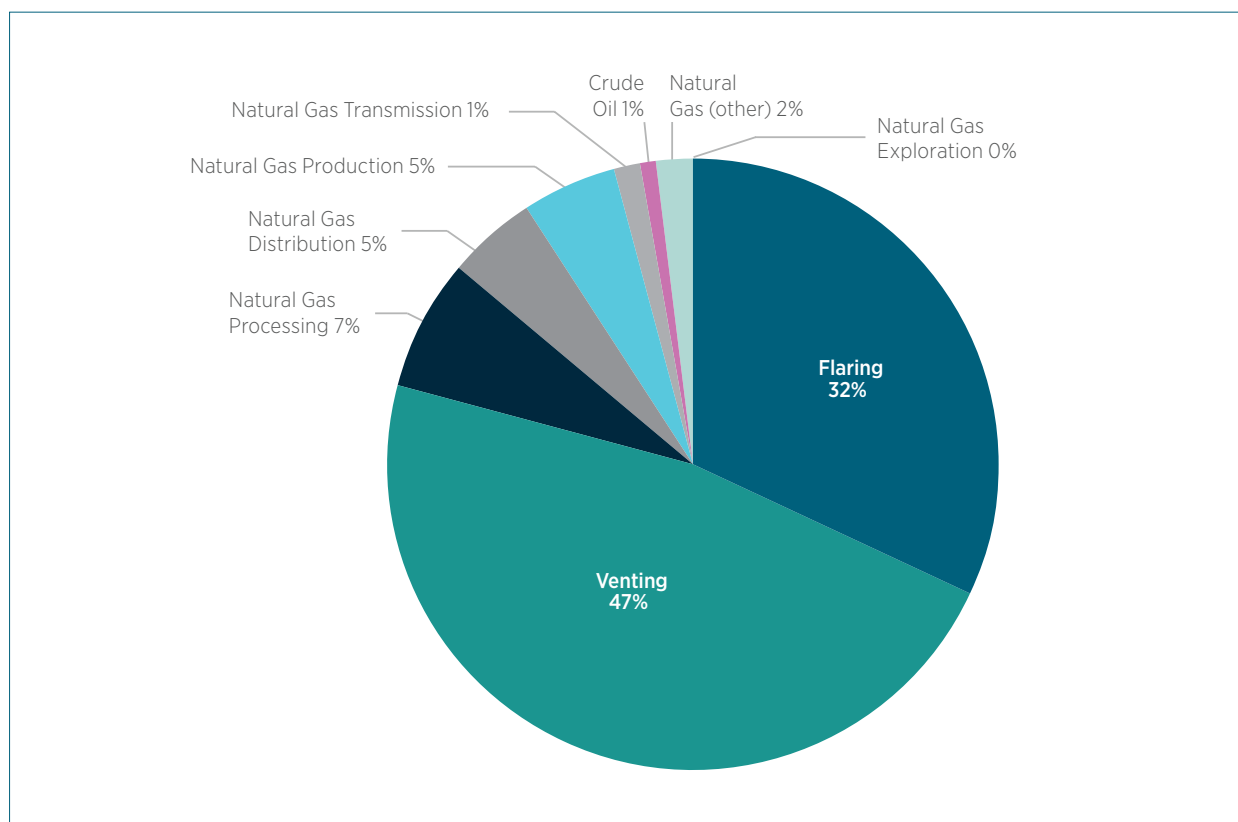

Post meter fugitive emissions from appliances, industrial and power plants and natural gas vehicles are reported under *1.B.2.b.6 Other*.

Fugitive emissions from abandoned oil and gas wells are reported under *1.B.2.a.6 Other* and *1.B.2.b.6 Other* respectively.

Combustion of raw natural gas used in gas processing, and liquefaction of gas for energy purposes, is reported under stationary energy *1A.Ic.ii Oil and Gas Extraction*.

As demonstrated in Figure 3.27, the majority (90 per cent) of fugitive emissions from oil and natural gas extraction occur in four source categories: flaring (32 per cent), venting (47 per cent), natural gas processing (7 per cent) and natural gas distribution (5 per cent).

Figure 3.27 Fugitive emissions contribution by oil and natural gas sub-sectors, 2020

Descriptions of emission estimation methods are provided in the following section under the respective inventory categories.

3.9.2 Methodology

Oil (1.B.2.a)

The activity data used to calculate emissions from 1.B.2.a oil is documented in Table 3.38.

Table 3.38 Fugitive emissions from oil extraction activity data sources

Inventory	Category	Operation/ source	Activity Data – Type	Activity Data – Source
1.B.2.a.1	Oil exploration	Gas flared	Tonnes of gas flared	NGER Scheme facility reports (CER, 2009–2020) and APPEA data (1990–2008)
		Liquids flared	Tonnes of liquid flared	NGER Scheme facility reports (CER, 2009–2020) and APPEA data (1990–2008)
1.B.2.a.2	Oil production	Leakage	Tonnes of crude oil produced	NGER Scheme facility reports (CER, 2009–2020) and APPEA data (1990–2008)
1.B.2.a.3	Crude oil transported	Leakage	Petajoules of crude oil transported	<i>Australian Energy Statistics</i> and <i>Australian Petroleum Statistics</i> (DISER) (1990–2020)

Inventory	Category	Operation/ source	Activity Data – Type	Activity Data – Source
1.B.2.a.4	Refining / Storage	Refining leakage	Tonnes of crude oil refined	NGER Scheme facility reports (CER, 2009–2020) and APPEA data (1990–2008)
		Storage leakage	Tonnes of crude oil stored	NGER Scheme facility reports (CER, 2009–2020) and APPEA data (1990–2008)
		Gas flared	Tonnes of gas flared	NGER Scheme facility reports (CER, 2009–2020) and AES data (1990–2008)
1.B.2.a.5	Distribution of oil products	Leakage	Petroleum sales	<i>Australian Petroleum Statistics</i> (DISER) (1990–2020)
1.B.2.a.6.i	Abandoned oil wells	Leakage	Number of abandoned wells	State and Territory drill hole datasets
1.B.2.c	Venting and flaring	Gas vented and flared during oil and gas production.	See Table 3.44	See Table 3.44

Oil and Gas Exploration (1.B.2.a.1 and 1.B.2.b.1)

Emissions may occur during the process of drilling for oil and gas either during exploration or development drilling, whenever gas or liquid hydrocarbons are encountered. Emission sources include flaring, degassing of drilling muds, and venting during well completions and workovers. Emission factors are reported in Table 3.39.

Table 3.39 Oil and gas exploration flaring, venting, and leakage emission factors

Inventory category	Unit	Factor			Source
		CO ₂	CH ₄	N ₂ O	
Offshore/ Onshore testing	tonnes of emissions / tonne of unprocessed gas flared	2.75	0.035	0.000081	NGER Scheme facility reports (CER, 2009–2020) APPEA (1998–2006)
	tonnes of emissions / tonne of crude oil flared	3.2	0.00033	0.00022	NGER Scheme facility reports (CER, 2009–2020) APPEA (1998–2006)

	tonnes of emissions / event (with fracturing and venting)	101.03 ^(a)	36.82		US EPA NIR Table A-134 (2016)
	tonnes of emissions / event (with fracturing and flaring)	13.47 ^(a)	4.91		US EPA NIR Table A-134 (2016)
	tonnes of emissions / event (with fracturing and green capture)	8.89 ^(a)	3.24		US EPA NIR Table A-134 (2016)

(a) CO₂ EFs were derived from CH₄ EFs using molecular weights (44.01/16.04).

Flaring

Short term testing activities of hydrocarbon flows and pressure may be undertaken following drilling. In the absence of collection infrastructure, which is generally the case in exploration, the hydrocarbons will usually be flared as a means of disposal. CO₂, some unburnt CH₄, and other non-CO₂ gases are released as a result of the flaring.

Drilling Mud degassing

Emissions occur during drilling via the degassing of drilling mud. On drilling through hydrocarbon strata, methane gas can be entrained within the drilling mud and vented at the surface. The 2009 *American Petroleum Institute Compendium* (API) provides emission factors based on specific drilling mud types as follows:

- Water based drilling mud 0.2605 tonnes CH₄/drilling day; and
- Oil based and synthetic mud 0.0586 tonnes CH₄/drilling day.

Source: API 2009, Table 5.-17.

The number of drilling days were estimated using the number of wells drilled for offshore/onshore and coal seam gas type wells, acquired from APPEA (1990–2015), state agencies (DTI 2017 and DNRM 2017b) and industry project sources. The average drill days per well were estimated using APPEA (2009–2015) data utilising the average drilling rate from spud date to target depth, by well type. A factor of 50 per cent was used to represent the portion of a well drill period which encounters hydrocarbons. The proportions of wells drilled with various types of drilling mud were derived from data on mud types used in Western Australia (WA Department of Industry and Resources; *Petroleum Guidelines – Drilling fluid Management 2006*, DIR 2006).

Crude Oil Production (other than venting and flaring) (1.B.2.a.2)

Emissions of CH₄ and NMVOCs may occur during oil production, including field processing, as a result of:

- leakages at seals in flanges, valves, and other components in a variety of process equipment; and
- storage tanks and losses of gases during oil production.

EFs for crude oil production are shown in Table 3.40.

Table 3.40 Oil production fugitive emission factors

Inventory Category	Operation/source	Emissions (t) / throughput (kt)					
		CO ₂	CH ₄	NMVOC	N ₂ O	NO ₂	CO
Crude oil production	Production leaks		0.057	810			
	Internal floating tank		0.00084				
	Fixed roof tank		0.0042				
	Floating tank		0.003				

Source: APPEA 1998–2006, E and P Forum 1994

Crude Oil Transport (1.B.2.a.3)

The marine, road or rail transport of crude oil results in emissions of NMVOCs, CH₄. The extent of emissions depends on the gas control technology employed during transfer operations, fuel properties (e.g. vapour pressure and gas composition), ambient temperatures, trip duration, and the leak integrity of tanks.

Emissions associated with the marine transport of crude oil are of three types: loading, transit, and ballasting. From the use of data from the United States Environmental Protection Agency (USEPA), it is estimated that

745 kg CH₄ is emitted per PJ of oil tankered (IPCC, 1997, Volume 3). Using the USEPA finding that CH₄ makes up 15 per cent of the mass of total organic emissions (USEPA, 1995b), the NMVOC EF for marine transport is estimated to be 4,200 kg per PJ of oil tankered.

Fugitive emission estimates are reported for three categories of oil: indigenous crude oil used within Australia, exported crude oil and imported crude oil. Fugitive emissions from the cargoes of ships engaged in international trade are a component of international bunker fuels, which are excluded from national inventories.

The volume of indigenous crude oil transported by ship to Australian refineries is assumed to equal indigenous crude oil production, minus crude oil exports, minus the lesser value of the following:

- Sales of petroleum products in Victoria (DISER 2020), or
- Production of crude oil in Victoria (DISER 2020).

The sales data is used when it is lower than the production data because any production exceeding sales in Victoria is assumed to be exported to a different Australian State/Territory. The production of crude oil in Victoria is used when it is lower than sales because any sales exceeding production are assumed to have been imported into the state.

Crude Oil Refining and Storage (1.B.2.a.4)

Crude oil is refined to numerous products via a wide variety of physical and chemical processes. During such processing, fugitive emissions of NMVOCs and CH₄ are generated. Fugitive emission sources at crude oil refineries include valves, flanges, pump and compressor seals, process drains, cooling towers, and oil/water separators.

Crude oil is stored at pipeline pump stations and refineries. During such storage, NMVOCs and CH₄ are emitted from normal processes such as tank breathing, and working and standing losses. Storage or tank losses are a complex function of a number of variables including tank characteristics, fuel properties, meteorological conditions, vapour emission control, and liquid throughput. In the absence of data at the individual refinery level, national CH₄ emissions from crude oil refining and storage may be calculated using default EFs according to IPCC Guidelines. The mid-range IPCC default EFs are adopted for crude oil refining and storage, i.e. 745 kg/ PJ for refining and 140 kg/PJ for storage.

Fugitive emissions of NMVOCs resulting from crude oil refining and storage have been estimated for Victoria (Carnovale *et al.* 1991). Based on the Victorian data, it is estimated that the NMVOC EF associated with fugitive and tank storage/loading is 20,000 kg/PJ of oil refined.

The NGER data has provided data on the emissions associated with the burning of refinery coke to restore the activity of the catalyst during the petroleum refining process. Refineries utilised NGER Scheme methodologies involving measurement of flue flow rates, flue gas composition and reference to the *Fluid Catalytic Cracking* handbook used in the petroleum refining industry.

Consistent with previous practice, and in order to maintain time series consistency, this source of emissions has continued to be included within petroleum refinery fuel combustion 1.A.1.b. This remains consistent with practice followed by most other countries. Furthermore, the IPCC *Guidelines* are ambiguous as to whether emissions from this source should be reported as fuel combustion or fugitive emissions.

Oil refinery flaring

The composition of refinery flare feed-gas is highly variable and depends on plant processing, process upsets and flare operation. In this inventory the composition of refinery gas directed to flares is assumed to be 30 per cent CH₄, 30 per cent NMVOCs and 40 per cent H₂ (by volume). An average flare combustion efficiency of 98 per cent is used, based on studies by USEPA (1995b).

For the years 1990 to 2008, the quantity of gas flared is calculated as 0.6 per cent of the total ABARE (1990–2008) annual refinery feedstock as no detailed data has been available on refinery flaring volumes. The methodology considered the range and age of technologies of the Australian refining industry and publicly available information on annual flaring emissions from Australian facilities. These assumptions were reviewed in GHD (2006b).

Facility level data on flaring volumes have become available for the first time in 2009 through the NGER Scheme. Analysis has shown that the flared quantity based on NGER data is consistent with the assumptions used to derive the activity data prior to 2009. Given that flaring quantities depend on facility-specific technology types and processes, as well as the episodic nature of flaring, it was decided that it was not appropriate to interpolate the NGER Scheme activity data back through the time series.

The EFs for flaring are country-specific factors used are consistently throughout the time series (Table 3.41).

Table 3.41 Emission factors for flaring of gas at oil refineries

Unit	CO ₂	CH ₄	N ₂ O	NO _x	CO	NMVOCs
Kg/t gas flared	2,695	6.8	0.081	1.5	8.7	12
Gg/PJ energy flared	47.2	0.12	0.001	0.026	0.15	0.21

Source: DISER estimates, following methodology of E & P Forum (1994).

Distribution of oil products (1.B.2.a.5)

The distribution of petroleum products represents a significant source of fugitive NMVOC emissions. Emission sources include motor vehicle refuelling, service station tank filling and breathing losses, major fuel-terminal storage, tank filling losses, refuelling of aircraft, and other mobile sources.

The NMVOC EFs for fuel storage tanks are a complex function of a number of variables and are shown in Table 3.42 on the basis of emissions per sales volumes of each product distributed in Australia. These EFs are calculated from a weighted average analysis of fuel transfer and storage regulations in different regions of Australia (see Appendix 3.A.22 and 3.A.23).

Table 3.42 NMVOC emission factors for petroleum product distribution (kg/kl distributed)

Emission sources	Emission factor (kg/kl distributed)		
	Petrol	Diesel	Avgas
Motor Vehicle/Equipment Refueling	1.40 ^(a)	0.084 ^(b)	N/A
Service Station/Premises, Storage/Transfer	0.66 ^(c)	0.006 ^(d)	N/A
Bulk Fuel Terminal, Storage/Transfer	1.08 ^(c)	0.009 ^(d)	N/A
Aircraft, Refueling/Storage	N/A	N/A	2.69 ^(e)
Total all sources	3.14	0.099	2.69

Source: (a) USEPA (1995b) Uncontrolled refuelling and spillage. (b) USEPA (1992) Uncontrolled refuelling and spillage. (c) See Appendix Table 3.A.23 and 3.A.24. (d) Scaled according to ratio of diesel/petrol emission rate for tank breathing and emptying as reported in USEPA (1992). (e) Australian Environment Council (AEC 1988).

A number of assumptions were made in compiling these EFs. Emissions from refined petroleum products in storage and in transit are assumed to be negligible, meaning that all emissions are associated with transfer and fuelling operations. Emissions associated with the normal distribution of LPG are also assumed to be negligible (EPA Victoria 1991; EPA NSW 1995). From a consideration of EFs (USEPA 1992), and the predominant modes of distribution of aviation turbine fuel and fuel oil, emissions of NMVOCs from the distribution of these fuels are estimated to be negligible.

Abandoned oil wells (1.B.2.a.6.i)

Abandoned wells are defined as wells that are no longer producing petroleum or exploration activities have ceased.

In 2019, Australia's Commonwealth Scientific and Industrial Research Organisation (CSIRO) undertook analysis of methane flows in the Surat Basin – a region of Queensland and northern New South Wales rich in economic activity that is also methane intensive. The CSIRO's findings were a key driver for Australia's review of its methane estimation approaches, further information on this review can be found in section 3.9.4.

The review analysed domestic and international scientific literature, including the *2019 Refinement to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories* (IPCC 2019 Refinement). The review found the emissions factors for abandoned oil wells, published in Table 4.2.4E of the IPCC 2019 Refinement, represented the best available science relevant to Australia's national situation.

Activity data on the number of abandoned oil wells and the plugging status of those wells were obtained from State and Territories governments, who manage data reported by the petroleum wells' responsible entities. Entities are generally obligated to report data through State and Territory regulations. The State and Territories datasets contain historical well data, often dating back to the early 1900s. Well locations are shown in Figure 3.28 and comprise the following sources:

- NSW Drillholes Petroleum (NSW Department of Regional New South Wales)
- VIC Drillhole Database (Geological Survey of Victoria)
- WA Petroleum & Geothermal Information Management System (Department of Mines, Industry Regulation and Safety)
- QLD Borehole Series (QLD Department of Resources)
- SA Resources Information Gateway (SA Department for Energy and Mining)
- NT Petroleum Wells dataset (NT Department of Industry, Tourism and Trade)
- TAS Drillhole dataset (TAS Department of State Growth)

Figure 3.28 Map of abandoned oil and gas wells

Activity data for the estimation model is counts of the abandoned wells for each year from 1990 to 2020. As the rig release date was not available in many cases, the rig spud date was used to identify the number of abandoned wells for the year estimated. The abandoned wells count was then further categorised into plugging status (plugged, unplugged, unknown), production type (oil, gas) and location (onshore, offshore).

The identification of plugging status between the State and Territory datasets is inconsistent, there are some commonalities which were used to allocate the well to an appropriate sub-category. Examples of the coding for the wells status are given in Table 3.43 below:

Table 3.43 Classification of various well status

State coding	Method coding
Plugged and Abandoned	Plugged
Capped/cased/ cemented/ shut-in	Plugged
Suspended/Abandoned	Unplugged
Dry	Unplugged
Unknown	Unknown
Suspended/Capped/Shut-in	Unknown
Null	Unknown

Where the well was identified as having oil and gas shows, or where the production type is unknown, the abandoned well is allocated to gas.

Table 3.44 Number of 2020 abandoned oil and gas wells

		Gas	Oil
Onshore	Plugged	4,524	202
	Not plugged	2,463	1,040
	Unknown	12,153	1,034
Offshore	Plugged	1,239	501
	Not plugged	253	103
	Unknown	5	152
Total		21,157	3,032

The estimates for abandoned wells are calculated using the emissions factors published in the IPCC 2019 Refinement Table 4.2.4E.

Table 3.45 Abandoned oil and gas wells emission factors

Category	Sub-category	Emissions factors (t CH ₄ /abandoned well)
Onshore	Plugged	2.0E-05
	Unplugged	8.8E-02
	Unknown	1.2E-02
Offshore	Plugged	3.5E-07
	Unplugged	1.8E-03
	Unknown	2.4E-04

Natural gas (1.B.2.b)

Natural gas production is generated from both onshore and offshore fields. Onshore fields comprise natural gas (mainly South Australia, Queensland and the Northern Territory) and coal seam gas production (mainly in Queensland).

Liquefaction of natural gas for export takes place at the North West Shelf, Pluto and Gorgon liquefied natural gas (LNG) plants near Dampier in Western Australia, Darwin in the Northern Territory, Gladstone in Queensland and offshore Broome Western Australia in a floating liquefied natural gas facility.

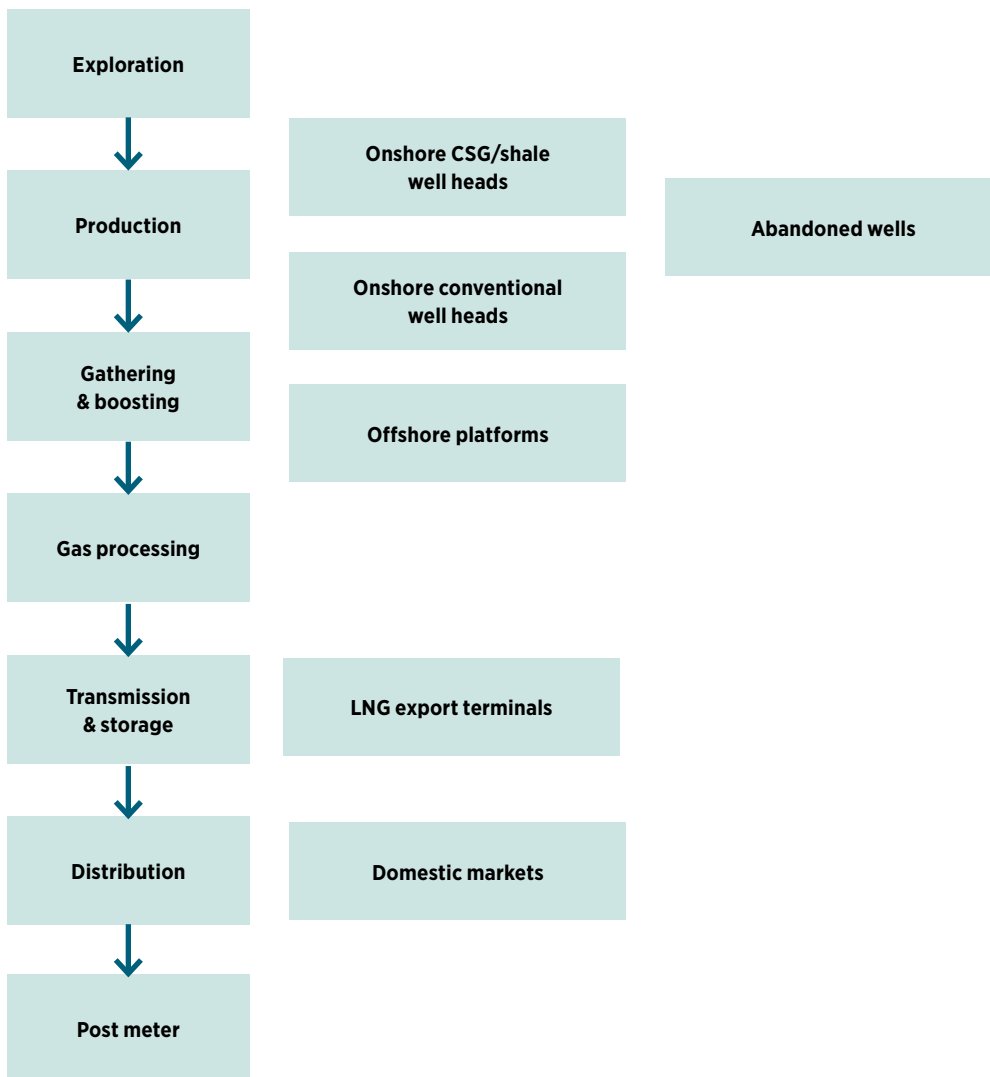

The major sub-categories of fugitive emissions of methane and carbon dioxide associated with gas supply relate to:

- Natural gas exploration (see 1.B.2.b.1) which includes emissions from drilling, flaring during exploration and emissions from well completions and workovers;
- Natural gas production (1.B.2.b.2) which includes leakages from onshore wells and well-pad operations; onshore gas gathering and boosting equipment and stations, water production, including compressors, dehydrators, pipelines and treatment plants; offshore gas platforms leakages;
- Natural gas processing plant leakages (1.B.2.b.3);
- Natural gas transmission and storage leakages (1.B.2.b.4);
- Natural gas distribution leakages (1.B.2.b.5) including emissions from residential and commercial sectors;

- Natural gas Post-meter emissions (1.B.2.b.6) including leakage emissions from appliances, industrial plants and power stations and natural gas vehicles; and
- Abandoned gas wells (1.B.2.b.8) leakage from onshore and offshore abandoned wells.

Fugitive emissions of both methane and carbon dioxide from venting and flaring from gas production and processing steps are described and reported under 1.B.2.c.

Figure 3.29 Emission estimation segments for the gas supply chain

Source: Department of Industry, Science, Energy and Resources.

The emission factors for leakages are derived from the following sources:

1. Australia-specific factors derived from research by the CSIRO, where available;
2. Application of more complex NGER Scheme methods – ‘method 2’, where appropriate using factors taken from API 2009, consistent with IPCC default factors;
3. Factors derived from US and international research, including those that update or supplement factors in API 2009:
 - a) Well completions for fractured wells (US EPA 2016);
 - b) Offshore gas platforms (US EPA 2016);
 - c) Gathering and boosting stations (Zimmerle *et al.* 20);
 - d) Gas processing plants (Mitchell *et al.* 2015);
 - e) Storage and export terminal infrastructure (US EPA 2016); and
 - f) Appliance leakage in the commercial and residential sector (Merrin and Francesco 2019).
4. Factors derived from the 2019 Refinement to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories:
 - a) Abandoned oil and gas wells; and
 - b) Industrial plants and power stations and natural gas vehicles.

The activity data used to calculate emissions from 1.B.2.b natural gas is documented in Table 3.46.

Table 3.46 Fugitive emissions from gas extraction activity data sources

Gas Exploration (1.B.2.b.1)

Emission factors relating to gas exploration are reported under *Oil and Gas exploration (1.B.2.a.1 and 1.B.4.a.1)* in Table 3.48. Methods for mud degassing are described under *Oil (1.B.2.a)*.

Well completions and workovers

Methane emissions occur in association with final well clean-ups, production testing and well stimulation associated with the transition of a well to gas production. The emission factors for well completions and workovers are technology – specific. The factor for well completions without the stimulation of fracking is derived from a study of Australian well completions by Day *et al.* 2017. The factor is 0.196 tonnes of methane per well completion.

In cases of well completions where stimulation of production through fracking occurs, the factors in US EPA 2016 are applied in the absence of any IPCC default factors for these types of events. The factors applied are:

- 36.8 tonnes of methane for a well completion event with fracking and venting;
- 3.2 tonnes of methane for a well completion event with fracking and where a green capture completion is performed; and
- 4.9 tonnes of methane for a well completion event with fracking and where flaring is performed.

The number of well completions was derived from production well activity data obtained from APPEA, state agencies and industry project sources and includes coal seam gas and shale gas wells. The number of well completions by year is provided in Table 3.46. The sharp recent expansion of the coal seam gas industry is evident in the sharp increase in the number of production wells since 2008.

Natural Gas Production (other than venting and flaring) (1.B.2.b.2)

This category represents leakage emissions from natural gas production, and includes emissions from the unintentional equipment leaks from valves, flanges, pump seals, compressor seals, relief valves, sampling connections, process drains, open-ended lines, casing, tanks, and other leakage sources from pressurised equipment not defined as a vent.

Emission Factors for natural gas production and processing leaks are shown in Table 3.48.

Onshore coal seam gas wells

The leakage rate for operating coal seam gas wells is derived from Day *et al.* 2014. This study collected field data measurements from 43 coal seam gas wells in coal seam gas producing states in Australia and found the mean emission leakage rates from gas producing wells corresponded to an emission factor of 4.7×10^{-5} tonnes of methane per tonne of gas production.

Produced water disposal

The produced water associated with coal seam gas production as a result of pumping is managed through treatment tanks and dams to enable, generally, the water to be used for some alternative purpose. Residual dissolved methane in the produced water will escape to the atmosphere throughout the treatment process.

The leakage rate, of 0.31 tonnes of methane per million litres of produced water, is taken from API (2009, Table 5–10) and is the factor cited in the ‘method 2’ of natural gas production and processing source in the NGER Scheme Measurement Determination. In 2020, there were 52,223 million litres of water produced across Australia.

Onshore natural gas wells

In the absence of a country specific factor for onshore natural gas wells, leakage rates for onshore natural gas wells are derived from onshore coal seam gas well measurements published in Day *et al.* 2014. This study collected field data measurements from 43 coal seam gas wells in coal seam gas producing states in Australia and found the mean emission leakage rates from gas producing wells corresponded to an emission factor of 4.7×10^{-5} tonnes of methane per tonne of gas production.

Offshore platforms

Offshore natural gas production is any platform structure that houses equipment to extract hydrocarbons from the ocean and that processes and/or transfers such hydrocarbons to storage, transport vessels, or onshore. Emission factors are taken from the US EPA 2016 in the absence of Australian data or IPCC default factors. For shallow water platforms (less than 200 metres of water), the emission factor is 62.6 tonnes of methane per platform per year while for deep water platforms, the factor is 661.1 tonnes of methane per platform per year. In 2020, there were 42 shallow platforms and 8 deep water platforms in Australian waters.

Table 3.48 Fugitive emission factors for natural gas

Inventory category	Unit	Factor		Source
		CO ₂	CH ₄	
Onshore Natural Gas wells	tonnes of emissions / tonne of gas throughput	0.00013 ^(a)	0.000047	Day <i>et al.</i> 2014

Post-meter leakage	Various	Various	Various	See Table 3.47

Onshore Gathering and boosting stations and pipelines

Onshore gas gathering and boosting fields (particularly coal seam gas) generally consist of gas gathering pipeline systems transporting gas directly to processing facilities or via field compressor boosting stations. Leakage emissions from gas processing facilities are reported under 1.B.2.b.3 Gas processing. The leakage from gas boosting stations are reported under 1.B.2.b.2 Gas production using the method detailed below. Leakage emissions from the gathering pipeline system are estimated based on km of pipeline length and an emission factor from API 2009, 6.1.2, Table 6.4 and as cited in NGER method '2'.

The emission factor for gathering and boosting stations is derived from Zimmerle *et al.* 2020, who collected measurements from 180 gathering and boosting stations across the United States.

The Department has estimated a non-linear relationship between the fugitive leakage emission rate emitted to the atmosphere and gathering and boosting station throughput (the quantity of natural gas passing through the station) (DISER 2020). The leakage emission rate declines quickly at low throughput levels and tends to a low rate of emission for higher levels of throughput. While stations with low throughput tend to have higher leakage rates, the low throughput of these stations means that their total emissions are nonetheless close to negligible.

The parameters in the equation for the emission factor for GB stations were revised in the 2020 NIR following re-analysis of data in Zimmerle in order to ensure that no double counting occurred with estimated venting emissions.

The new equation adopted for the Australian inventory is:

$$E_{ij} = 2.386 \times Q_{ij}^{-0.761}$$

Where E_{ij} is the estimated fugitive leakage emissions of methane from gas gathering and boosting stations; and Q_{ij} is the quantity of coal seam gas throughput at the gas gathering and boosting station.

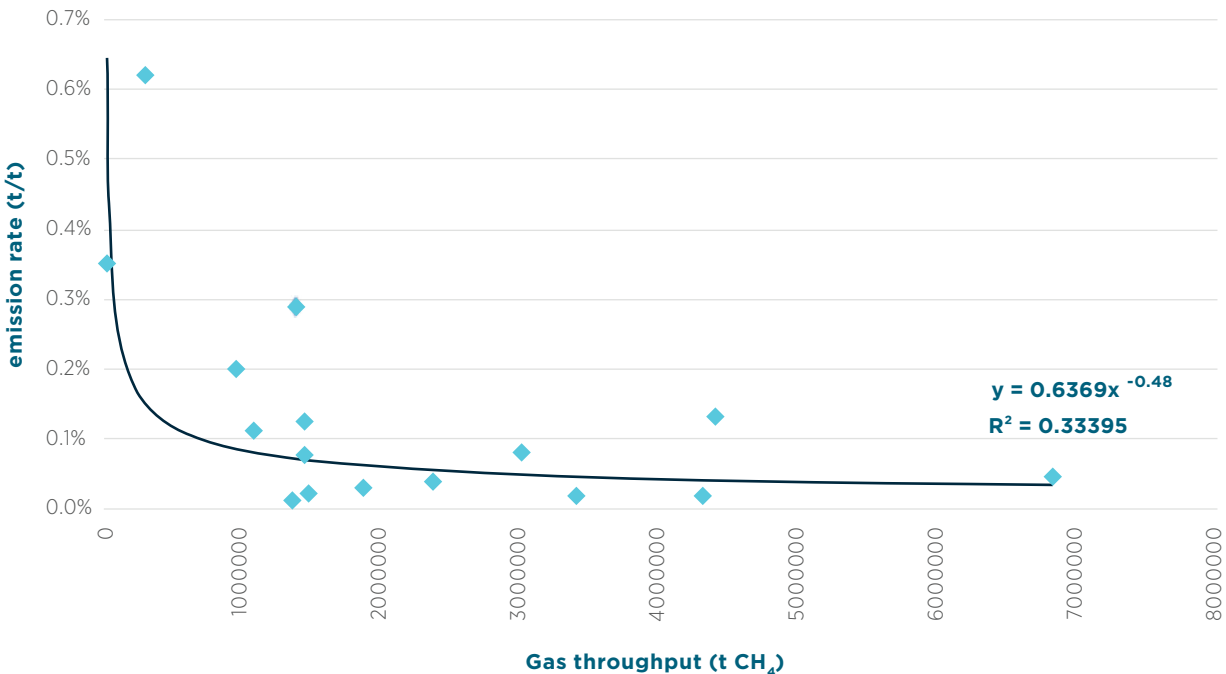

Gas Processing (1.B.2.b.3)

The emission factor function for gas processing plants is derived from Mitchell *et al.* 2015, whose data for gas processing plants confirms that those facilities with the highest emission rates tend to be those with the smallest gas throughputs. Analysis of Mitchell's data indicates a non-linear, negative relationship between emission rates and the size of gas processing throughput – in general, higher emission rates are experienced by plants with lower gas throughput and lower emission rates for plants with high gas throughput (Figure 3.30).

$$Y = 0.6369 \cdot X^{-0.48}$$

Where Y = emission rate in tonnes of emissions per tonne of gas throughput
 X = gas throughput in tonnes

Figure 3.30 Gas processing plants with reported high emission rates are likely to have negligible gas throughputs

Source: Derived from Mitchell *et al.* (2015).

Using this equation, the modelled emission rate for the smallest plant was 0.0065 tonnes per tonne of gas throughput and the modelled emission rate for the largest, 0.0004 tonnes per tonne of gas throughput. These estimates suggest that there are emissions benefits from additional scale in plant design.

Natural Gas Transmission and Storage (1.B.2.b.4)

Natural gas transmission

Australia has an extensive system of long distance natural gas transmission pipelines. As with oil and gas production, emissions may occur as a result of compressor starts (for which gas expansion is typically used to start gas turbine power units), blowdowns for maintenance at compressor stations, maintenance on pipelines, leakage, and accidents.

The Australian high pressure gas transmission system is of relatively recent vintage (the oldest line dates from 1969), has been built to high quality standards and is well maintained. Work undertaken by the Pipeline Authority concluded that losses from a typical gas transmission pipeline in Australia are 0.005 per cent of throughput.

The factor of 0.005 per cent and the throughput data are used in conjunction with national average pipeline gas composition figures for each year, as given in Table 3.49. Throughput data are obtained from the NGER Scheme (2009 onwards), the Australian Gas Association (AGA) and the Energy Supply Association of Australia (ESAA). *IPCC Good Practice Guidance (2000)* recommends an approach where emissions are also linked to the length of pipeline rather than solely using throughput. Consistent with this approach, emissions are calculated for a reference year and emissions for other years scaled against the reference year according to the change in pipeline length.

Natural gas storage

Natural gas storage sites are an increasingly important component of the Australian gas marketplace. Natural gas storage emission factors are taken from US EPA (2016), in the absence of IPCC default factors, and set at 370 tonnes of methane per facility per year. In 2020, there were 8 gas storage facilities in operation in Australia.

Liquefied Natural Gas Storage and Export (1.B.2.b.5)

Liquefied natural gas export terminal emission factors are taken from US EPA (2016), in the absence of IPCC default factors, and set at 1109 tonnes of methane per facility per year. In 2020, there were 10 LNG export terminals in Australia. Liquefied natural gas storage emission factors are taken from US EPA (2016) in the absence of IPCC default factors, and set at 921 tonnes of methane per facility per year. In 2020, there were an estimated 12 LNG storage stations in operation in Australia.

Natural Gas Distribution (1.B.2.b.5)

The boundary between natural gas transmission and distribution is generally taken to be the city gate regulator stations at which gas pressures are reduced from transmission pressures (up to about 15 MPa) to sub-transmission pressures. Most of the gas lost from gas transmissions and distribution systems is by way of leakage from the low-pressure network. The amount of leakage depends on the number and condition of joints in the pipes. The high pressure and trunk main pipes are welded steel, so flanged joints are typically only at valves and compressors. Pressures are so high that any major leaks that might occur are obvious, dangerous and quickly attended. Other causes of fugitive emissions from gas distribution systems (up to and including customer meter) are:

- third party damage (e.g. excavators);
- purging of new mains;
- unburnt gas from gas compressors (if there are any on the distribution system);
- gas lost to atmosphere on start-up and shut down of compressors; and
- regulating and relief valves.

There is currently a 10 year data overlap between the total annual gas utility sales (AES, DISER 2020) and the quantity of natural gas distribution reported under the NGER Scheme (CER, 2018). The high level, total annual gas utility sales have been used historically in lieu of direct data relating to natural gas distribution. By removing components of these high level estimates that are known to be used in other sectors (i.e. Divisions A, B, D and I of the AES data), it was assumed that the remainder of gas sales fell under the natural gas distribution sector.

Conversely, the NGER Scheme facility data of gas sales directly attributed to natural gas distribution has now been reported for 10 years. All of the natural gas distributors of Australia appear to be captured under the NGER Scheme, and these data provide a consistently lower time series than the AES data.

The overlap method specified in Chapter 5.3.3.1 on *Time Series Consistency – Overlap* in the 2006 IPCC Guidelines was used to splice the series together – specifically by comparing the difference between the two data sources during overlapping years, taking the average proportion of difference, and applying it through the AES time series.

Emissions from the distributor side of the meter are not measured directly, but must be based on estimates of unaccounted for gas (UAFG). Components of UAFG include: leakage emissions, meter inaccuracies, use of gas within the system itself, theft of gas, variations in temperature and pressure and differences between billing cycles and accounting procedures between companies delivering and receiving the gas.

The ratio of emissions to UAFG for Australian utilities was first estimated at 80 per cent (Dixon 1990) and 70–80 per cent (Hutchinson *et al.* 1993). A leakage component for UAFG of 90 per cent was used for 1990 (NGGIC 1994), reflecting an additional allowance for the additional emissions from the customers side of the meter, which were not covered in the two studies. In 2006, discussion of an analysis of industry data on the progressive upgrade of the gas distribution infrastructure in response to a variety of drivers, including greenhouse gas emissions concerns, concluded that a figure in the range of 50–60 per cent was more realistic for circumstances of the time (Energy Strategies 2005), and the leakage share of UAFG was estimated at 55 per cent.

In 2020, a review of literature, including the 2017 Zincara Review for Victoria's Essential Services Commission, and public submissions by distribution companies concluded that a figure in the range of 35–40 per cent would be more accurate after further improvements to distribution networks in all states. Based on expert judgement and available reported UAFG breakdowns from companies, the estimate for the leakage proportion of total UAFG was set to 37.3 per cent from 2018 onwards. A linear interpolation of historic data for the 2006 to 2018 period was also applied to account for improvements to distribution pipelines in the time period between 2005 and 2018 (Table 3.A.25).

The data sources necessary to calculate emissions from natural gas distribution are:

- estimates of UAFG as a percentage of gas issued annually by gas utilities in each State, published in the Energy Supply Association of Australia series; *Electricity, Gas Australia* (ESAA 2005–2014, AEC 2018);
- annual gas utility sales in each State and Territory, published in the Energy Supply Association of Australia series; *Electricity, Gas Australia* (ESAA and AEC 2005 onwards); this figure is sales through the low pressure distribution system, and excludes sales made through high pressure mains to electricity generators and large industrial customers;
- NGER data for 2009 onwards, which includes the facility-specific data for natural gas distribution throughput and associated emissions data for all natural gas distributors in Australia; and
- the composition of pipeline gas supplied in each State and Territory pipeline system (Table 3.49).

Table 3.49 Natural gas composition and emission factors

Pipeline	Longford, Melbourne (Victoria)	Moomba, Sydney (NSW, SA)	Roma, Brisbane (Qld)	Denison, Gladstone (Qld)	Dampier, Perth (WA)	Dongarra, Perth (WA)	Amadeus, Darwin (NT)	Australia (average)

2014	7.0	362.8	369.9
2015	7.5	366.4	373.9
2016	7.8	368.9	376.6
2017	8.0	360.8	368.8
2018	8.4	370.0	378.4
2019	8.8	368.5	377.2
2020	9.1	374.1	383.2

Abandoned gas wells (1.B.2.b.6.i)

Abandoned gas wells are defined as wells that are no longer producing gas or exploration activities have ceased.

In 2019, Australia's Commonwealth Scientific and Industrial Research Organisation (CSIRO) undertook analysis of methane flows in the Surat Basin – a region of Queensland and northern New South Wales rich in economic activity that is also methane intensive. The CSIRO's findings were a key driver for Australia's review of its methane estimation approaches, further information on this review can be found in section 3.9.4.

The review analysed domestic and international scientific literature, including the 2019 Refinement to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories (IPCC 2019 Refinement). The review found the emissions factors for abandoned oil wells, published in Table 4.2.4E of the IPCC 2019 Refinement, represented the best available science relevant to Australia's national situation.

Activity data on the number of abandoned gas wells and the plugging status of those wells were obtained from State and Territories governments, who manage data reported by the petroleum wells' responsible entities. The data sources and description of processing methods used to compile the activity data for both abandoned gas and oil wells are provided under *Abandoned oil wells (1.B.2.a.6.i)*.

Post-meter emissions (1.B.2.b.6.ii)

This segment includes fugitive emissions beyond gas meters and from natural gas-fuelled vehicles.

Appliance leakage

Fugitive methane and carbon dioxide leakage emissions that occur downstream from the meter are estimated for natural gas appliances used in the residential and commercial sectors, such as cooktops, water heaters and space heating.

A nationally specific method was applied using emissions factors by appliance type derived from a measurement study by Merrin and Francesco (2019) which looked at non-combustion emissions from residential natural gas appliances (Table 3.50b).

Table 3.50b Methane emission factors by natural gas appliance type for residential and commercial sectors

Appliance type	EF (t CH ₄ /appliance/year)	Derivation (see Merrin & Francesco 2019)
Residential		
<i>Cooking</i>		
Upright - NG	9.30E-05	average of "stove" and "oven" factors
Cooktop - NG	5.60E-05	"stove" factor
Oven - NG	1.30E-04	"oven" factor
<i>Space conditioning</i>		
Gas Space: Flued-NG	2.20E-04	"furnace" factor
Gas Space: Unflued-NG	2.20E-04	"furnace" factor
Gas Ducted-NG	2.20E-04	"furnace" factor
<i>Water heating</i>		
GSWH - NG	7.70E-05	"water heater" factor
GIWH - NG	1.20E-03	"tankless W.H." factor

SGWH Z2 - NG	1.20E-03	"tankless W.H." factor

Appliance type	EF (t CH ₄ /appliance/year)	Derivation (see Merrin & Francesco 2019)
SGWH Z3 - NG	1.20E-03	"tankless W.H." factor
SGWH Z4 - NG	1.20E-03	"tankless W.H." factor
<i>Other equipment</i>		
Pool Heating-Gas	1.20E-03	"tankless W.H." factor
Spa-Gas	1.20E-03	"tankless W.H." factor
<i>Commercial</i>		
Space heating	2.20E-04	"furnace" factor
Hot water	6.39E-04	Average of "water heater" and "tankless W.H." factors
Kitchen/catering	9.30E-05	Average of "stove" and "oven" factors
Other	3.17E-04	Average of factors above

Activity data for appliances in the residential sector was sourced from the Residential Baseline Study for Australia 2000–2030 (October 2015) commissioned by the Department of Industry and Science. Activity data for appliances in the commercial sector was inferred from residential data in conjunction with relative natural gas consumption in both sectors.

Industrial and power plants

A review of international scientific literature including the IPCC 2019 Refinement found the emission factors for leakages at industrial plants and power stations published in Table 4.2.4K of the IPCC 2019 Refinement represented the best available science relevant to Australia's national situation. Emission factors of 0.4 tonnes of methane and 0.0033 tonnes of carbon dioxide per million cubic metres of natural gas are applied to activity data comprising the natural gas consumption of electricity and industrial plants. Industrial sectors for which fugitive leakage is already calculated under the Oil and Gas sector such as Oil and Gas extraction, Gas transmission and Distribution are excluded to avoid double-counting.

Natural gas vehicles

The review found the emissions factors for leakage from natural gas fuelled vehicles, published in Table 4.2.4K of the IPCC 2019 Refinement, represented the best available science relevant to Australia's national situation. Emission factors of 3.0×10^{-4} tonnes of methane and 2.3×10^{-6} tonnes of carbon dioxide per natural gas fuelled vehicle are used. The emission factor includes releases from dead volumes during fuelling, emptying of gas cylinders of high-pressure interim storage units, for execution of pressure tests and relaxation of residual pressure from vehicles' gas tanks, for pressure tests or decommissioning.

Activity data were obtained from New South Wales State motor vehicle registration statistics (NSW Roads and Maritime Service 2020). A national time series of natural gas vehicles was then inferred by using the consumption of natural gas in the transport sector to ensure time series consistency and completeness.

Oil and gas production venting and flaring (1.B.2.c)

Venting refers to emissions that are the result of process or equipment design or operational practices. Venting at oil and gas processing facilities is mainly associated with the release of CO₂, which is extracted from the raw gas stream in the course of gas processing. Because separation of the other components of the gas stream from the CO₂ is incomplete, the vented CO₂ contains small quantities of CH₄. The quantities of CO₂ and CH₄ vented will depend on the concentration of CO₂ in the raw gas, which varies significantly between gas fields, and on the mode of operation and efficiency of the CO₂ stripping plant. Gas processing facilities monitor the volumes of the vent gas and CO₂ and CH₄ concentrations as a part of routine plant operation. The venting of CH₄ also occurs from gas assisted pumps and cold process vents.

Flaring refers to the controlled combustion of a mixed flammable gas stream. At oil and gas processing plants, flared gas may arise from crude oil processing or natural gas processing. Where there is no market for gas separated from the wellhead production stream, the gas is reinjected or flared. With the growth in markets for natural gas and an increase in its value, some Australian petroleum production facilities now operate as combined oil and gas facilities, with both oil and gas as marketable products. At such facilities, smaller quantities of gas are flared as part of normal operation of the various processing units. Typically, gas sent to flare is mostly CH₄ with smaller concentrations of other volatile hydrocarbons and is usually different in composition to pipeline gas.

The activity data used to calculate emissions from 1.B.2.c venting and flaring is documented in Table 3.51.

Table 3.51 Fugitive emissions from venting and flaring activity data sources

Inventory Category	Operation/source	Activity Data – Type	Activity Data – Source
1.B.2.c.1.i Oil venting	Gas vented during oil production	IE – 1.B.2.c.1.ii Gas venting	IE – 1.B.2.c.1.ii Gas venting
1.B.2.c.1.ii Gas venting	Gas vented during oil production	Tonnes of gas vented	NGER Scheme facility reports (CER, 2009–2020) and APPEA data (1990–2008)
	Gas vented during gas production	Tonnes of gas vented	NGER Scheme facility reports (CER, 2009–2020) and APPEA data (1990–2008)
	Gas vented during condensate production	Oil barrels (bbl)	APPEA data (1990–2015) APS data (DoEE/DISER 2016 to 2020)
1.B.2.c.2.i Oil flaring	Crude oil flared during oil production	Tonnes of liquid flared	NGER Scheme facility reports (CER, 2009–2020) and APPEA data (1990–2008)
	Gas flared during oil refining	Tonnes of gas flared	NGER Scheme facility reports (CER, 2009–2020) and APPEA data (1990–2008)
	Gas flared during oil refining	Tonnes of gas flared	NGER Scheme facility reports (CER, 2009–2020) and APPEA data (1990–2008)
1.B.2.c.2.ii Gas flaring	Gas flared during gas production	Tonnes of gas flared	NGER Scheme facility reports (CER, 2009–2020) and APPEA data (1990–2008)

Venting – Gas

From 1990 to 2008, estimates of emissions are based on APPEA 2008 data. The APPEA data consists largely of direct monitored emissions associated with control vent releases, equivalent to a *tier 3* estimation, as well as estimates of emissions from cold process vents. The NGER Scheme approach for 2009 onwards has enhanced the methodologies available for technology types by utilising the American Petroleum Institute Compendium (API 2009) methodologies for vents.

Methane vented from condensate production is estimated from the average factor in the United States, US EPA (2017), and from production published by APPEA.

Flaring - Oil and Gas

Emission factors can be found in Table 3.52 and are country-specific, sourced from the APPEA industry inventory. The NGER emission factors are consistent with those used for the APPEA inventory, thus ensuring time series consistency between the time series.

Prior to 2009, the APPEA data did not provide splits for flaring between oil and gas sources and, therefore, flaring emissions were reported in the oil/gas combined category. With the introduction of the NGER Scheme for the inventory year 2009, separate emissions data has been available for the individual oil and gas flaring categories and therefore the flaring emissions have been reported for 2009 onwards in those respective categories.

In response to ERT recommendation E.13 (2016), a method was implemented in Australia's *National Inventory Report 2014* for splitting oil and gas flaring in 1990–2008. The reporting of a full time series for oil flaring was achieved by calculating the average implied emissions per petajoule of crude oil and ORF (oil refinery fuel) produced (from the *Australian Energy Statistics*) for NGER years (2009 onwards) and applying this factor back through the production time series (1990–2008). These derived oil flaring emissions were subtracted from the combined total of oil and gas flaring emissions, resulting in no net change in emissions from flaring.

Table 3.52 Venting and flaring emission factors

Inventory category	Unit	Factor			Source
		CO ₂	CH ₄	N ₂ O	
Gas vented during oil production	NA	Various	Various	Various	NGER
Gas vented during oil production	NA	Various	Various	Various	NGER
Gas vented during gas production	NA	Various	Various	Various	NGER
Gas vented during condensate production	Tonnes of emission / barrel of condensate	0.007	0.0025		US NIR 2017
Crude oil flared during oil production	Tonnes of emission / tonne of oil flared	3.2	0.0014	0.00022	APPEA 2000
Gas flared during oil production	Tonnes of emission / tonne of gas flared	2.9	0.035	0.000081	APPEA 2000
Gas flared during oil refining	Tonnes of emission / tonne of gas flared	2.695	0.0068	0.000081	NGER
Gas flared during gas production	Tonnes of emission / tonne of gas flared	2.7	0.00476	0.000097	NGER

3.9.3 Uncertainties and time series consistency

The tier 1 uncertainty analysis in Annex 2 provides estimates of uncertainty according to IPCC source category and gas.

Time series consistency is maintained through the use of consistent methodologies and data over time across multiple datasets.

3.9.4 Source specific QA/QC

This source category is also covered by the general QA/QC of the greenhouse gas inventory in Chapter 1.

Results from top-down studies and inverse modelling of methane in Australia's coal seam gas (CSG) fields have been used for QA for validation of national inventory estimates. Australia's coal seam gas (CSG) fields in the Surat Basin of Queensland generate methane emissions from gas leakages, deliberate losses from gas venting or flaring, and from incomplete oxidation of gas during combustion.

In Australia's national inventory, methane losses from CSG production are estimated to be 0.4% of gas production for the upstream supply chain and 0.47% of gas production for the export supply chain in Australia.

In recent years, independent assessments of methane losses from CSG operations in the Surat Basin have been undertaken by researchers at the CSIRO Atmospheric Division (Luhar et al 2020), and at the UNSW, sponsored by the UN Environment Program (Neininger et al 2021). These studies use techniques that attempt to monitor the methane plumes observed in the Surat Basin directly (known as a top-down approach). Working under the Gas Industry Social and Environmental Research Alliance (GISERA) program, the CSIRO study used flux towers stationed at different points in the Basin while the UNEP study used plane flyovers in order to map and quantify the extent of the methane plumes observed in the Surat Basin.

The CSIRO GISERA program made its own assessment of the extent of the methane losses from CSG production in the Surat Basin, derived from the work of the CSIRO Atmospheric Division, and concluded that methane losses were less than 0.5% of natural gas production (CSIRO GISERA 2021). The UNEP study concluded that CSG sources in the Surat Basin emit about 0.4% of the produced gas (Neininger et al 2021).

The convergence of methane loss results from both the CSIRO / GISERA assessment and the UNEP study with the national inventory provides strong quality assurance that the national inventory estimates of methane losses from CSG gas supply are robust.

3.9.5 Recalculations since the 2021 submission

Table 3.53 Summary of recalculations

UNFCCC category	Years recalculated	Recalc summary (Gg CO ₂ -e)				NIR section reference	Reason for recalculation
		1990	2000	2010	2019		
1.B.2.b.5 Distribution	2007 to 2019			-331.07	-850.76	Page 161: Natural Gas Distribution (1.B.2.b.5)	Revision of UAFG fraction and update of AD based on Facility level annual reports and NGER reported emissions
1.B.2.b.8 Abandoned Gas Wells	1990 to 2019	-0.06	0.03	0.76	2.76	Page 116: Other (1.B.2.b.6)	recalculation of default factors
1.B.2.a.6.i Abandoned Oil Wells	1990 to 2019	0.17	0.22	0.46	0.49	Page 102: Abandoned oil wells (1.B.2.a.6.i)	recalculation of default factors
1.B.2.b.2 Production - Onshore Gathering and Boosting Stations	1990 to 2019	-11.30	-14.18	-22.26	-31.15	Page 159: Gathering and boosting stations and pipelines	Improved emissions factors

A detailed explanation and quantification of recalculations are provided in Table 3.54.

In summary, the recalculations since the 2021 submission were undertaken to incorporate:

- Updated activity data
 - 1.B.2.b.5 Natural Gas Distribution
- Improved emission factor methodology to reflect latest published research
 - 1. B.2.b.2 Onshore Gathering and Boosting Stations.
 - 1.B.2.b.8 Abandoned Gas Wells
 - 1.B.2.a.6.i Abandoned Oil Wells
- Revised methodology parameters
 - 1.B.2.b.5 Natural Gas Distribution

Revised natural gas sales figures relating to natural gas distribution was provided in the *Australian Energy Update 2018* (DoEE 2019), which resulted in recalculations for estimates of emissions for *1B2biii5 Distribution*.

Revised apportionment of the leakage share of unaccounted for gas was provided in December 2020, which resulted in recalculations for estimates of emissions for *1.B.2.b.iii.5 Distribution*.

Recalculations to 1.B.2 Oil and Gas Distribution are detailed in Table 3.55.

A revision has been made to the calculations for Gas Distribution to align it with modern data availability and granularity. The previous calculation method, most recently updated in 2005, aggregated throughput at a state level and applied a fixed state-wide factor. The new method uses throughput data reported through the NGER Scheme since 2009, and extends the change to 2007 for time series consistency. Data earlier than this period is more difficult to find at a facility level.

Since 2009, the National Greenhouse and Energy Reporting scheme has required companies to report facility level emissions and throughput, as well as including “Method 2” reporting as an option, where companies use direct measurement, or other propriety methods to calculate and report their network emissions. In addition, a number of companies report their throughput and unaccounted for gas (UAFG) in annual reports and to the Australian Energy Regulator (AER) in their 5 yearly access arrangement proposals.

The new method uses data provided at a facility level, and applies a tiered factor to calculate leakage. The NGER directly reported Method 2 data is the most preferred source, followed by calculations using the historic reported UAFG, then the AER agreed baseline UAFG, then, where none of those options are available, the state-based UAFG factor, as per the previous method.

Table 3.55 1.B.2 Oil and Gas Distribution: recalculation of total emissions 1990–2019

	2021 submission	2022 submission	Change

3.9.6 Planned improvements

The *National Greenhouse and Energy Reporting Act 2007* requires all major companies in Australia to make estimates of methane emissions from their gas supply operations. The Australian Government has updated the rules for the estimation of fugitive methane emission losses, commencing with reports due in October 2022 (Australian Government 2021c). Companies will be able to quantify the impacts of the methane leak detection and repair programs that they implement and to report these impacts to the Australian Government. These data are then made available for use in Australia's National Inventory, with the aim of being able to reflect the use of methane reduction technologies and practices.

The CSIRO under the GISERA program is also undertaking a new 'bottom-up' empirical study examining leakage measurements of CSG equipment at sites in the Surat Basin. This new study will provide additional data on leakage rates of equipment in Australian conditions, and will add significantly to the existing empirical knowledge base. The Department expects this new study will provide valuable data to inform the development of leakage factors for future national inventory method updates.

New empirical and remote sensing studies of methane emissions in Australia will continue to emerge over time and are expected to provide valuable information in relation to methane sources. The implications of these new studies will be taken into account in future national inventory method development as part of the inventory's continuous improvement processes.

3.10 Source Category 1.C Carbon Capture and Storage

3.10.1 Source category description

The IPCC Guidelines defines Carbon Capture and Storage (CCS) as a chain subdivided into four systems – Capture and compression, Transport, Injection, and Geological Storage.

Australia has one commercial CCS project, operated by Chevron Australia at an LNG processing and export facility on Barrow Island in Western Australia.

The Gorgon LNG project commenced trials of the carbon dioxide underground injection system at the Gorgon natural gas facility in August 2019, with 2.7Mt CO₂ injected for the 2019/20 NGER reporting period.

It is expected that the Gorgon system will inject between 3.4 and 4 million tonnes of greenhouse gas emissions each year over a projected 40 year life of the project when operating at full capacity.

CCS projects

The Gorgon LNG project is developing the Gorgon and Jansz-Io gas fields, located within the Greater Gorgon area, between 130 and 220 kilometres off the northwest coast of Western Australia. It includes the construction of a 15.6 million tonne per annum liquefied natural gas (LNG) plant on Barrow Island and a domestic gas plant.

Chevron Australia's Gorgon LNG project CCS operations at Barrow Island in Western Australia are developed in accordance with approvals under the project specific legislative instrument the *Barrow Island Act 2003* (WA). Carbon dioxide is separated from the natural gas and captured at the Barrow Island gas processing plant, and transported by a 7km pipeline to the injection site – the Dupuy saline aquifer, 2.3 km beneath Barrow Island. The project involves nine injection wells, and includes long-term monitoring with a number of surveillance wells and seismic surveying.

CCS Research project

An existing CCS demonstration and research project in Australia is the CO₂ CRC Otway Project in Victoria.

This demonstration project however does not constitute a CCS activity in accordance with IPCC guidance.

Naturally occurring CO₂ is extracted from a geological reservoir CO₂, and hence is not captured for abatement purposes. The CO₂ is dried and purified, and transported by a short 2km pipeline for reinjection into a nearby depleted natural gas field and a deeper saline aquifer.

From its commencement in 2006, the project has injected trial volumes of around 65,000 tonnes of CO₂. This research project is reinjecting negligible amounts of naturally occurring reservoir CO₂ that has been extracted from nearby geological formation, and does not involve capture or abatement. A negligible amount of fugitive emissions would be associated with the processing, transport and reinjection – these emissions are not estimated.

3.10.2 Methodology

For the Gorgon and future commercial CCS projects, the Department of Industry, Science, Energy and Resources sources estimates of fugitive emissions of greenhouse gases associated with the capture, transport, injection and long term geological storage of greenhouse gases from data collected under the NGER Scheme. Please see Chapter 1 National Inventory Arrangements for further details on the NGER Scheme.

The NGER Scheme provides methods for estimating emissions from CCS projects that have been developed to be consistent with IPCC 2006 Inventory Guidelines.

For estimating fugitive emissions from the transport and injection phases of CCS, NGER methods reference existing guidance for the natural gas industry, providing for the use industry best practice methods for pipeline and injection well operations.

In Australia, any CCS project is undertaken under a licence provided under state or commonwealth legislation depending on the jurisdiction the project is located in. Under these licences, strict project specific conditions for monitoring and reporting of leaks are given. Hence, for estimating leakage from the storage formation, the NGER Scheme mirrors estimates made in accordance with the MRV requirements of the licence. This is particularly important given the project specific nature of monitoring and reporting requirements for CCS projects.

Appendix 3.A Additional information on activity data

- (a) CH₄ and N₂O IPCC (2006, Volume 2) value for residual oil boiler. USEPA (1995b) Pg 1.3-2 to 1.3-6. Uncontrolled emissions of CO, NO_x, and NMVOc from residual oil (No. 4-6) fired utility boilers (normal firing).
- (b) CH₄ and N₂O IPCC (2006, Volume 2) value for gas/diesel oil boiler. CO, NO_x, NMVOc Distillate oil fired utility boiler data not available. Assume emissions equal those of residual oil fired utility boiler scaled by relative emissions of industrial boiler category (USEPA, 1986, Pg 1.3-2).
- (c) CH₄ and N₂O IPCC (2006, Volume 2) value for large diesel oil engine. CO, NO_x, NMVOc USEPA (1995b) Pg 3.4-3
- (d) CH₄ and N₂O IPCC (2006, Volume 2) value residual fuel oil/shale oil boiler.
- (e) CH₄ and N₂O IPCC (2006, Volume 2) value for residual fuel oil/shale oil. CO, NO_x, NMVOc USEPA (1995b) Pg 3.4-3. Assume dual fuel EFs.
- (f) CH₄ and N₂O IPCC (2006, Volume 2) value for pulverised coal fired dry bottom configuration CO, NO_x, NMVOc USEPA (1995b) Pg 1.1-6 and 1.1-22. Uncontrolled emissions for pulverised coal fired dry bottom configuration.
- (g) CH₄ and N₂O IPCC (2006, Volume 2) assume value for pulverised coal fired dry bottom configuration CO, NO_x, NMVOc USEPA (1995b) Pg 1.1-6 and 1.1-22. Uncontrolled emissions for pulverised coal fired dry bottom configuration (tangentially fired boiler).
- (h) CH₄ and N₂O IPCC (2006, Volume 2) assume value for pulverised coal fired dry bottom configuration Assume CH₄ and N₂O and NMVOc EFs identical to black coal combustion. CO and NO_x EFs based on average of SECV data (1994).
- (i) CH₄ and N₂O IPCC (2006, Volume 2) assume value for pulverised coal fired dry bottom configuration.
- (j) CH₄ and N₂O IPCC (2006, Volume 2) value for natural gas boiler. CO, NO_x, NMVOc USEPA (1995b) Pg 1.4-4 to 1.4-6. Uncontrolled emissions of CO, NO_x, and NMVOc from natural gas fired 'commercial' boilers (0.1-2.9 MW).
- (k) CH₄ and N₂O IPCC (2006, Volume 2) assume value for natural gas gas-fired turbine >3MW. USEPA (1995b) Pg 3.1-3 and 3.1-5. Uncontrolled emissions of CO and NO_x for large stationary natural gas turbines. NMVOc emissions estimated from ratio of NMHC: to Total Organic Compounds for selective catalytic reduction controlled turbines.
- (l) CH₄ and N₂O IPCC (2006, Volume 2) assume value for natural gas Large Dual-fuel engine. CO, NO_x, NMVOc USEPA (1995b) Pg 3.4-3. Assume dual fuel EFs.
- (m) CH₄ and N₂O IPCC (2006, Volume 2) assume value for natural gas combined cycle. CO, NO_x, NMVOc USEPA (1995b) Pg 1.4-4 to 1.4-6. Uncontrolled emissions of CO, NO_x, and NMVOc from natural gas fired 'commercial' boilers (0.1-2.9 MW).
- (n) CH₄ and N₂O IPCC (2006, Volume 2) value for wood/wood waste boiler. CO, NO_x, NMVOc USEPA (1995b) Pg 1.6-6 to 1.6-7. Uncontrolled emissions from wood waste combustion in stoker boiler. Assume wood moisture content of 50 per cent as recommended by USEPA.
- (o) CH₄ and N₂O IPCC (2006, Volume 2) value for wood/wood waste boiler. CO, NO_x IPCC (1997a) data for NO_x and CO converted to gross calorific equivalent by dividing by 1.05. NMVOc emission rates estimated by scaling relative to wood boiler data (see (n)).

4. Industrial Processes and Product Use

4.1 Overview

Total net emissions estimated from *industrial processes and product use* were 32.7 Mt CO₂-e in 2020, or 6.2 per cent of net national emissions (excluding LULUCF) (Table 4.1).

Table 4.1 Industrial processes and product use sector CO₂-e emissions, 2020

Greenhouse Gas Source and Sink Categories	Greenhouse gas source CO ₂ -e emissions (Gg)				Total 2020 CO ₂ -e
	CO ₂	CH ₄	N ₂ O	HFC/ PFC/ SF ₆	
2. Industrial Processes and Product Use	18,769	71	1,963	11,926	32,729
A. Mineral Industry	5,228	NA	NA	NA	5,228
B. Chemical Industry	2,987	11	1,947	NA	4,945
C. Metal Industry	10,162	61	16	270	10,509
D. Non-energy products from fuels and solvent use	178	NA	NA	NA	178
E. Electronics Industry	NA	NA	NA	NE	NE
F. Product uses as substitutes for Ozone Depleting Substances	NA	NA	NA	11,564	11,564
G. Other product manufacture and use	NA	NA	NA	91	91
H. Other	214	NA	NA	NA	214

The *metal industry* contributed 32.1 per cent (10.5 Mt CO₂-e) of the sector's emissions, The *mineral industry* contributed 16.0 per cent (5.2 Mt CO₂-e), *chemical industries* contributed 15.1 per cent (4.9 Mt CO₂-e), the *product uses as substitutes for ozone depleting substances* contributed 35.3 per cent (11.6 Mt CO₂-e), *Other (food and drink)* contributed 0.7 per cent (0.2 Mt CO₂-e) and *other product manufacture and use* contributed 0.3 per cent (0.1 Mt CO₂-e).

The main gas emitted by *industrial processes and product use* is CO₂, contributing 57.3 per cent (18.8 Mt CO₂-e) of the sector's emissions in 2020. PFCs contributed 0.8 per cent (0.3 Mt CO₂-e), HFCs contributed 35.3 per cent (11.6 Mt CO₂-e), SF₆ contributed 0.3 per cent (0.1 Mt CO₂-e), N₂O contributed 6.0 per cent (2.0 Mt CO₂-e), and CH₄ 0.2 per cent (0.1 Mt CO₂-e).

Trends

Net emissions from *industrial processes and product use* increased by 26.4 per cent (6.8 Mt CO₂-e) from 1990 to 2020, and decreased by 2.0 per cent (0.7 Mt CO₂-e) between 2019 and 2020.

The increases in sectoral emissions observed over the longer term are principally due to growth in emissions associated with the manufacture of chemical products and *Product uses as substitutes for Ozone Depleting Substances*.

Each source category's contribution to total emissions and to sectoral trends within the industrial processes and product use sector between 1990 and 2021 is shown in Figure 4.1.

Figure 4.1 Emissions from industrial processes and product use by subsector, 1990–2020

Cement production

Emissions of CO₂ for this source category are dependent on the quantity of cement produced and this in turn is closely tied to Australian construction industry activity. Domestic production of clinker has been in general decline over the last decade with an increasing proportion of imported clinker being used in cement production. Emissions of CO₂ from cement production in 2020 were 2.8 Mt CO₂-e, a 18.6 per cent decrease from 1990, while production has decreased by 15.5 per cent over the same period. Improvements in industry practices such as the recycling of cement kiln dust have resulted in lower emissions per unit production.

Year on year fluctuations in emissions from cement production are variable and strongly correlated to fluctuations in cement production.

Lime production

Emissions of CO₂ from the production of lime vary year to year according to the quantities of commercial and in-house lime produced. The quantities of lime produced are dependent on the demand for lime within the Australian economy. Total lime production in 2020 was 1,548 kt compared with 1,488 kt in 2019 representing an increase in production of 4.0 per cent. Lime production levels are sensitive to levels of demand in the resources sector as evidenced by the decline in lime production of 16.7 per cent observed in 2000 and a 13.0 per cent decline in 2009. The decline in 2000 is attributed to the fall in demand for minerals processing particularly in the gold sector while the 2009 decline is associated with the general economic downturn also affecting other industrial processes.

Limestone and dolomite use

The total CO₂ emissions reported in this source category include emissions from the consumption of carbonates in calcite, magnesite, dolomite, sodium bicarbonate, potassium carbonate, barium carbonate, lithium carbonate and strontium carbonate, magnesia production, zinc production, ferroalloys production, iron and steel production, ceramics (including clay bricks) and glass production, soda ash use and production and miscellaneous uses of carbonates. The trend in emissions is heavily influenced by the consumption of limestone which is consumed in greater quantities than any other carbonate. In 2020, total carbonate consumption had decreased by 5.5 per cent from 1990. The year on year growth in carbonate consumption, however, has varied from positive to negative throughout the time series as changes in activity in the broad range of consuming industries occur.

Soda ash production and use

Soda ash is produced in Australia by only one company, Alcoa. A second producer, Penrice Soda Products, ceased operations in late 2013. Soda ash is now predominantly imported into Australia. More than half the soda ash produced is consumed by glass manufacturers, with other important users of soda ash including manufacturers of detergents, soaps and chemicals and the metals and mining industries. Production of soda ash remained relatively constant while imports of soda ash have experienced large fluctuations and an overall increase in quantities. In 2020, soda ash consumption was 42 per cent lower than in 1990.

Chemical industry

In 2009, there was a scaling back of chemical products manufacture reflecting, in combination, the effects of the international economic downturn and a gas explosion in Western Australia in October 2008 which affected natural gas supplies for ammonia production in that part of the country. Emissions from the chemical industry peaked in 2007 and have since undergone a decline as a result of improvements in nitric acid emissions control and declining levels of synthetic rutile production due to plant closures.

Iron and steel production

Emissions per tonne of iron and steel produced vary according to changing quantities of reductants used. Emissions from iron and steel production in 2020 were 3.7 per cent lower than in 2019.

A notable decline of emissions from iron and steel production occurred in 2012 with a 21.3 per cent reduction on 2011. This decrease in emissions reflected a decrease in the coke consumption in iron and steel production reported under the NGER Scheme, and was associated with the closure of the No.6 blast furnace at the Port Kembla steelworks in October 2011.

The down-turn in emissions during 2005 occurred due to the blast-furnace re-lining activities at the Whyalla steel works. There has been a general declining trend in the Iron and Steel CO₂-e IEF due to the increased use of pulverised coal injection in lieu of coke.

Aluminium production

Emissions from the production of aluminium were 0.1 per cent higher in 2020 than 2019 owing to an increase in production levels and the associated consumption of coal tar, petroleum coke and other inputs to the anode production process.

The 69.4 per cent downward trend in CO₂-e emissions per tonne of aluminium produced since 1990 has occurred as a result of improvements in process control and the resultant reduction in PFC emissions. Any fluctuations in IEFs occurring in the latter part of the time series are the result of small fluctuations in the number of anode effects in the

production process occurring due to electricity supply disruptions and potline maintenance. The fall in the PFC IEF between 2005 and 2007 occurred as a result of a smelter upgrade at Hydro Kurri Kurri (conversion of Potline No 1 from side-work to centre-work) and an enhanced emissions performance at the Tomago smelter (AAC 2007).

Consumption of halocarbons and SF₆

Emissions from the consumption of halocarbons and SF₆ have increased steadily over time with a growing stock of gas and low levels of destruction and recycling. HFC refrigerants were first used in Australia in 1994 and have been increasing in use since that time as ozone depleting refrigerants are phased out under the Montreal Protocol. A phase-down of bulk imports of HFCs commenced on 1 January 2018.

SF₆ has been in use in electricity supply and distribution and miscellaneous uses throughout the time series.

4.2 Overview of source category description and methodology – Industrial Processes and Product Use

The *industrial processes and product use* sector includes emissions generated from a range of production processes involving *inter alia* the use of carbonates (i.e. limestone, dolomite, magnesite, etc.); carbon when used as a chemical reductant (e.g. iron and steel or aluminium production); chemical industry processes (e.g. ammonia and nitric acid production) and the production and use of synthetic gases such as halocarbons. Key categories for Australia include emissions from cement production, iron and steel production, aluminium production and the consumption of halocarbons.

For some industries, for example the iron and steel industry, reported emissions are split between the *industrial processes and product use* sector and the *energy* sector depending on the type of process within the industry that generated the emissions.

The Australian methodology for *industrial processes and product use* contains both country specific and IPCC default methodologies and EFs (Table 4.2). The use of tier 2 methods indicates a higher level of complexity, data requirements and in-principle accuracy than a tier 1 method.

In certain sub sectors within *industrial processes and product use*, activity data are commercial-in-confidence and, due to the direct relationship between activity and emissions, emissions estimates by gas species are also confidential. Where this is the case, it is necessary to aggregate sub-sectoral emission estimates in order to preserve confidentiality.

Emissions of CO₂ from *magnesia production* (2.A.4.c) have been aggregated with CO₂ from *other product uses of carbonates* (2.A.4). CO₂ emissions from *carbide production* (2.B.5) and *soda ash production* (2.B.7) under 2.B.10 – *confidential chemical industry emissions*. Emissions of N₂O from the *use of N₂O in anesthesia and aerosols* (2.G.3) have been aggregated with N₂O from *nitric acid production* (2.B.2). This aggregate is reported under 2.B.2 *nitric acid production*. Emissions from *iron and steel production* (2.C.1) are aggregated with emissions from the production of *ferroalloys* and *other metals* (2.C.2 and 2.C.7).

Data sources

The inventory for the *industrial processes and product use* sector relies primarily on data collected under the National Greenhouse and Energy Reporting Scheme. The following table summarises the data source used in compiling the inventory for *industrial processes and product use*.

Table 4.3 Summary of principal data sources for industrial processes and product use 2020

Industrial processes and product use sector		Method of data collection	Activity data
2.A.1	Cement	NGER	Cement Australia, Boral, Adelaide Brighton
2.A.2	Lime production	NGER	Boral, Adelaide Brighton, Cement Australia, Sibelco Pacific, Alcan and Queensland Alumina
2.A.4	Limestone and dolomite and other carbonates	NGER	Alcan Gove, Alcoa, Amcor, Arrium, BGC Australia, BlueScope Steel, Boral, Bradken, Brickworks, CSR, Fletcher Building, FMQ Australia, Glencore Investment, Heathgate Resources, Incitec Pivot, Kalgoorlie consolidated gold mines, Nyrstar Australia, Owens Illinois, Redbank Energy, Rio Tinto, Silbelco, Sun Metals, Thales Australia, Wesfarmers, Orora, Tarac Australia, Norton Goldfields
2.A.6	Bitumen	Published statistics	ABARES Commodity Statistics
2.B.1	Ammonia	NGER	Incitec, Orica, Wesfarmers CSBP, BHP Billiton, Queensland Nitrates, Burrup Fertilisers
2.B.2	Nitric acid	NGER	Orica, Wesfarmers CSBP, Queensland Nitrates
2.B.6	Synthetic Rutile and Titanium Dioxide	NGER	Tiwest, Iluka Resources, Millennium Chemicals
2.B.7	Soda ash production	NGER	Penrice Soda Products, Alcoa
2.B.8	Petrochemical and carbon black production	Company Census	Dynea W.A, Borden Chemicals, Orica, BP, Shell, Huntsman Chemicals, Dow Chemicals, Qenos, ExxonMobil, Continental Carbon, Cabot Australia, Australian Vinyl, BOC Gases, Air Liquide, Caltex, Coogee Chemicals
2.C.1	Iron and steel	NGER	BlueScope Steel, Arrium
2.C.2	Ferroalloys production	NGER	TemCo
2.C.3	Aluminium	NGER	Alcoa, Rio Tinto, Hydro Kurri Kurri, Tomago Aluminium
2.C.5-7	Lead, Zinc and Other metals	NGER and published statistics	Billiton Manganese, BHP Billiton, Simcoa ABARES Commodity Statistics for various metals
2.F.6	Other – SF ₆ use in electrical transmission and distribution	NGER	Multiple NGER Scheme entities consuming SF ₆ in electrical switchgear and circuit breaker applications
2.F.1-5	Product uses as substitutes for ODS	Import licence reporting	Bulk import and pre-charged equipment data reported to the former Department of Agriculture, Water and the Environment under the regulations applying under the <i>Ozone Protection and Synthetic Greenhouse Gas Management Act 2003</i>
2.G.1	Electrical equipment	NGER	SF ₆ stock data and EFs obtained from NGER reporting entities.
2.G.2	SF ₆ and PFCs from other product uses		
2.G.3	N ₂ O from product uses	Company survey	BOC, Air Liquide
2.H.2	Food and drink	NGER and published statistics	ABS apparent consumption data, Penrice Soda Products, Air Liquide, BOC, Huntsman Chemicals, Incitec, Orica.

4.3 Source Category 2.A Mineral Industry

4.3.1 Cement production (2.A.1)

Source category description

Cement clinker production is a key category for Australia. CO₂ is produced during the manufacture of portland clinker, which is an intermediate product in the production of cement. CO₂ emissions are essentially proportional to the lime content of the clinker. On exit from the cement kiln, and after cooling, the clinker is ground to a fine powder and up to 5 per cent (by weight) of gypsum or natural anhydrite (that is, forms of calcium sulphate) added to control the setting time of the cement. The finished product is referred to as 'portland' cement.

There are three clinker producers in Australia; Adelaide Brighton, Blue Circle Southern Cement (Boral) and Cement Australia. The production of blended cements, incorporating waste materials from other industries (e.g. slag, fly ash and silica fume), represents a significant portion (approximately 20 per cent) of the total cement manufacturing market in Australia. According to the Cement Industry Federation (CIF 2020), the proportion of waste materials added to general purpose and blended cement is limited by the Australian Standard (AS 3972-2010) to 7.5 per cent. Blending waste materials with cement significantly reduces the CO₂ emissions per unit of cement produced.

The production of clinker in Australia responds to market conditions. Competition with imported products has become a significant issue for domestic production, especially in recent years. Between 2012 and 2015, three clinker production facilities ceased operations.

Methodology

Calcium carbonate (CaCO₃) from calcium rich raw materials such as limestone, chalk and natural cement rock is heated at temperatures of approximately 1500° C in cement kilns to form lime (CaO) and CO₂ in a process known as calcination.

Emissions from clinker production are estimated using a tier 2 method.

$$E_{cl} = [EF_{cl} \cdot A_{cl} + EF_{cl} \cdot F_{ckd} \cdot A_{ckd} + EF_{toc} \cdot (A_{cl} + A_{ckd})] \cdot 10^{-6}$$

CO₂ emissions from clinker manufacture are estimated by the application of a country – specific emission factor EF_{cl} , in kilograms of CO₂ released per tonne of clinker produced, to the annual national clinker production A_{cl} .

The country – specific EF is the product of the fraction of lime used in the clinker and a constant reflecting the mass of CO₂ released per unit of lime produced. This factor was derived using the World Business Council for Sustainable Development (WBCSD 2005) methodology. Assuming CaO and MgO proportions of 0.66 and 0.015 respectively, based on Ryan and Samarin 1992, leads to an EF of 534 kg CO₂ per tonne of clinker.

In addition to the emissions associated with the lime used in the clinker, the methodology accounts for emissions associated with the calcination of cement kiln dust (A_{ckd}) and the quantity of total organic carbon expressed as a proportion of total clinker produced (TOC). F_{ckd} is the degree of calcination of cement kiln dust (ranging from 0 per cent to 100 per cent) and is assumed to be 100 per cent in Australia such that $F_{ckd} = 1$ (following WBCSD 2005). A_{ckd} is the quantity of cement kiln dust (CKD) produced annually. The EF for TOC is taken from WBCSD 2005 (equivalent to 10kg CO₂ per tonne of clinker).

Choice of emission factor

Under the provisions of the National Greenhouse and Energy Reporting (Measurement) Determination, facilities are able to determine facility-specific EFs based on the CaO and MgO contents of their cement clinker according to the following equation:

$$F_{\text{CaO}} \times 0.785 + F_{\text{MgO}} \times 1.092$$

Where F_{CaO} is the estimated fraction of cement clinker that is calcium oxide derived from carbonate sources and produced from the operation of the facility

F_{MgO} is the estimated fraction of cement clinker that is magnesium oxide derived from carbonate sources and produced from the operation of the facility

From 2016, two cement production facilities have reported facility-specific EFs based on facility-specific measurement of the CaO and MgO contents of their produced clinker.

The National Greenhouse and Energy Reporting (Measurement) Determination also sets out the sampling requirements for cement clinker:

- 1) A sample of cement clinker must be derived from a composite of amounts of the cement clinker produced.
- 2) The samples must be collected on enough occasions to produce a representative sample.
- 3) The samples must also be free of bias so that any estimates are neither over nor under estimates of the true value.
- 4) Bias must be tested in accordance with an appropriate standard.

The minimum frequency of analysis of samples of cement clinker must be in accordance with the Tier 3 method for cement clinker in section 2.2.1.1 in Chapter 2 of Volume 3 of the 2006 IPCC Guidelines.

The remaining facilities continue to use the CS factor as described above as this factor best represents their particular product specifications. The CS EF is used for all facilities from 1990–2015 as adopted by all cement producers under the NGER Scheme prior to 2016.

Activity data

Data for cement production for individual facilities were obtained from the NGER Scheme for 2009 onwards and the reporting mechanisms of the former Emissions Intensive, Trade Exposed Industries assistance program (EITEIs – subsequently known as the Jobs and Competitiveness Program) for 2007 and 2008. Data for the period 1990–2006 were obtained by industry survey undertaken by the Cement Industry Federation (CIF). In all cases, all producers of cement have been captured throughout the time-series.

Table 4.4 Australian cement clinker production and emissions 1990, 2000–2020

Year	Clinker production (kt)	Cement Kiln Dust (kt)	Emissions (Gg CO ₂)

4.3.2 Lime production (2.A.2)

Source category description

Lime is an important chemical having major uses in metallurgy (steel, copper, gold, aluminium and silver), other industrial applications (water softening, pH control, sewage sludge stabilisation), and construction (soil stabilisation, asphalt additive and masonry lime). The producers of commercial lime in Australia include Cement Australia, Boral Cement, Adelaide Brighton Cement and Sibelco Pacific. Rio Tinto Alcan also produces in-house lime intermittently for alumina production. This is the sole facility that undertakes in-house lime production.

Methodology

CO₂ is produced when either high calcium lime (CaO) or dolomitic lime (CaO.MgO) are manufactured by the calcination of calcium rich raw materials (limestone or dolomite) in a kiln.

Emissions from lime production are estimated using a tier 2 method.

Total CO₂ emissions E_q associated with lime production A_q are estimated as the sum of emissions by facility according to:

$$E_q = \sum A_q \cdot EF_q$$

The EF for lime produced is estimated for each facility from a consideration of the molecular weights (56 for CaO, 44 for CO₂) and the composition of the lime products.

Choice of emission factor

Selection of EFs was undertaken in accordance with the decision tree in section 1.4.1.

Information important to the derivation of lime production emission factors has been obtained under the former EITIEs program and the NGER Scheme from 2007 onwards where available. Emission factors are derived under 2 different scenarios:

- a) where facility-specific lime product composition information is available:

Where lime producers have information on the specifications of their product, they are able to derive facility-specific emission factors on the basis of pure calcium carbonate (CaO) and magnesium carbonate (MgO) content of their product. The pure carbonate emission factors used to derive facility-specific emission factors are as follows:

- 0.785 t CO₂ x the fraction of pure CaO in the lime
- 1.092 t CO₂ x the fraction of pure MgO in the lime

The following equation is applied to derive a facility-specific emission factor:

$$EF = 0.785 \text{ t CO}_2 \times \text{the fraction of pure CaO in the lime} + 1.092 \text{ t CO}_2 \times \text{the fraction of pure MgO in the lime}$$

It follows therefore that where lime producers manufacture lime with a high MgO content, their facility-specific emission factor will be higher than the default case.

From 2007 onwards, facility-specific emission factor information related to commercial lime production became available. The weighted average of these emission factors for all facilities producing commercial lime (including those who did not provide facility-specific emission factors) was 0.751 t CO₂/t lime produced in 2007 – based on the relative contributions to total production of all commercial lime producers. This weighted value applies only to manufacturers of commercial lime and is higher than the commercial lime CS EF because it reflects the non-standard specifications of producers with commercial lime with a high MgO content. To date, no facility level information on in-house lime production has been available.

b) where facility-specific lime product composition information is not available:

Under this scenario, Australia provides country-specific emission factors for the use of lime manufacturers reporting under the NGER Scheme. These are based upon assumed fractional purities of commercial and in-house lime and are calculated according to the equation:

$$EF = F \times (44.01/56.08)$$

Where F is the fractional purity of lime produced
 44.01 is the molecular weight of CO₂
 56.08 is the molecular weight of CaO

The CS emission factors are as follows:

- 0.675 t CO₂/ t commercial lime produced, based on a fractional purity of lime of 0.86
- 0.730 t CO₂/t in-house lime produced, based on a fractional purity of lime of 0.93

As outlined above, facilities that do have product composition information, have reported facility-specific emission factors. The average emission factor for all facilities weighted on the basis of relative levels of production is 0.751 t CO₂/t lime.

Country-specific emission factors for commercial and in-house lime are applied to facilities which do not have information on the composition of their product:

- 0.675 t CO₂/ t commercial lime produced
- 0.730 t CO₂/t in-house lime produced

The following timeline sets out the application of each of the emission factors:

	1990	2006	2007	2020
Commercial lime	Weighted average EF 0.751 t CO ₂ / t lime		Facility specific Efs Default CS EF-0.675 t CO ₂ /t lime	
In-house lime	Default CS EF-0.675 t CO ₂ /t lime			

The fluctuation in the implied emission factor year on year reflects the relative proportions of commercial and in-house lime production as well as the relative proportions of production of individual lime producers from 2007 onwards where facility level emission factors are used.

Time series consistency is maintained through the use of a weighted average EF of 0.751 t CO₂/t lime produced for the years when individual facility data are not available (1990–2006). It is assumed for the years 1990–2006 that lime producers continued to produce lime in the same relative proportions as observed in 2007 when facility-level data first became available.

For in-house lime, as no producers have composition information, the CS emission factor is applied for all years where in-house lime production occurs.

Data on lime production (including data on the amount of lime produced in-house) have been collected under the NGER Scheme for 2009 onwards and the reporting mechanisms of the former EITEIs Program for 2007 and 2008.

Data for the period 1990–2006 were obtained by industry census undertaken by the National Lime Association up to 2000 and various consultants from 2001 to 2006 (For example, GHD 2009c). The census and NGER collection mechanisms have enabled complete coverage of lime producers throughout the time-series.

Table 4.5 Lime production emissions 1990, 2000–2020

Year	Total Lime production (kt)(a)	Emissions (Gg CO ₂)
1990	1,035	775

(a) Includes quantities of in-house lime production.

4.3.3 Glass production (2.A.3)

Source category description

CO₂ emissions associated with the production of glass are included in section 4.3.4 Other Process uses of carbonates (2.A.4)

4.3.4 Other process uses of carbonates (2.A.4)

Source category description

Apart from use in cement and lime production, limestone (CaCO₃), magnesite (MgCO₃) and dolomite (CaCO₃, MgCO₃) are basic raw materials that have commercial applications in a number of industries including metallurgy (for example, iron and steel), glass manufacture, ceramics and clay bricks, agriculture, construction, magnesia production and environmental pollution control.

All CO₂ emissions associated with the consumption of carbonates, with the exception of the emissions reported under soda ash, cement and lime production, are accounted for under Other Process uses of Carbonates. This includes emissions from the use of limestone by the iron and steel, ferroalloys, magnesia, zinc, glass, ceramics and clay brick production. Emissions from the use of limestone in cement and lime production are accounted for under 2.A.1 and 2.A.2 respectively.

Emissions associated with the use of carbonates for soda ash production are accounted for under 2.B.7 Soda Ash Production.

Companies using carbonates in their production processes include Owens-Illinois, CSR, Amcor, Qmag, Causmag, OneSteel, BlueScope Steel, Rio-tinto, Billiton Manganese, Bradken, Sun Metals, BHP Billiton, Xstrata, Nyrstar, Incitec Pivot, Minara Resources, Fletcher Insulation, Thales Australia, and Penrice.

To protect confidentiality, the emissions from the production of soda ash (2.B.7) have been aggregated with this source category (2.A.4). The confidentiality provisions of the NGER Act under which facility specific data is obtained do not allow reporting the use of carbonates in the category in which they are used.

To improve the completeness of the inventory emissions from other carbonates known to be supplied to the Australian economy have also been included in this source category (2.A.4). These include sodium bicarbonate, potassium carbonate, barium carbonate, lithium carbonate and strontium carbonate.

Methodology

A tier 2 method is utilised for the Australian inventory. The mass of CO₂ emitted per unit of limestone EF_{l_s}, dolomite EF_d and other carbonates use EF_o is estimated from a consideration of the purity of the raw materials and the stoichiometry of the chemical processes (44 for CO₂; 100 for limestone; 184 for dolomite, 84 for magnesite, 106 for soda ash and 114 for the remaining carbonates). Only the amount of carbonate material used in an application which generates CO₂ is used in the estimation of CO₂ emitted.

Total CO₂ emissions, E, are estimated by summing over each facility the quantity of limestone, A_{l_s}, dolomite, A_d, and other carbonate use, A_o, multiplied by their respective country-specific fractional purities and EFs derived from stoichiometry:

$$E = A_{l_s} \cdot F_{l_s} \cdot EF_{l_s} + A_d \cdot F_d \cdot EF_d + A_o \cdot F_o \cdot EF_o$$

The fractional purities are country specific and include limestone, F_{l_s}, 0.90, dolomite F_d, 0.95, and for all other carbonates, 1.00. The EFs are derived from stoichiometry and are 0.396 t CO₂/t limestone, 0.522 t CO₂/t magnesium carbonate, and 0.453 t CO₂/t dolomite.

Emissions from the manufacture of clay bricks

Emissions from carbonate consumption associated with the manufacture of clay bricks are based upon the quantities of clay bricks produced annually as recorded by the Australian Bureau of Statistics (ABS 1991a, 2000 and 2012) and a country-specific EF derived from data provided by the peak industry body representing Australian clay brick and paver manufacturers, Think Brick.

Choice of Emission Factor

No facility-specific data on EFs were obtained under NGER. Country-specific CO₂ fractional purities and stoichiometric EFs were applied for all facilities and for all years.

Limestone and dolomite consumption data have been collected under the NGER Scheme from 2009 and the reporting mechanisms of former EITEIs Program for 2007 and 2008.

Data for the period 1990–2006 were obtained by a combination of industry survey (for example GHD 2009c) and back casting of production based on NGER data.

The coverage of companies for this source was expanded in the 2011 submission due to the mandatory reporting by all companies with emissions above the NGER Scheme reporting thresholds whereas previous voluntary surveys had not identified all consumers of limestone. Where data for a particular facility collected under the NGER Scheme was not available in GHD 2009c, time series consistency was maintained by the interpolation of consumption rates reported under the NGER Scheme for 2009 to the period between the commencement date for the facility and 2008. These facilities include Bradken, Incitec Pivot, Rio Tinto, Fletcher Insulation, Thales, Sun Metals and Minara Resources.

Table 4.6 Carbonate consumption and emissions 1990, 2000–2020

Year	Limestone Use (kt) ^(a)	Dolomite and Other Carbonate Use(kt) ^(b)	Total emissions from the consumption of carbonates (Gg CO ₂)
1990	2,176	778	1,251
2000	2,800	1,169	1,654
2001	2,506	1,170	1,548
2002	2,577	1,219	1,628
2003	2,606	1,270	1,651
2004	2,557	1,235	1,617
2005	2,506	1,232	1,601
2006	2,641	1,284	1,679
2007	2,905	1,255	1,789
2008	2,736	1,279	1,715
2009	2,420	948	1,427
2010	2,548	1,077	1,525
2011	2,563	1,404	1,699
2012	2,357	1,323	1,590
2013	2,225	1,327	1,555
2014	1,691	1,792	1,680

2018	1,572	1,623	1,555
2019	1,623	1,487	1,524
2020	1,635	1,157	1,351

Source: EnerGreen Consulting 2009, DCCEE EITEIs Program 2009, NGER Scheme 2009 to date.

(a) Excludes limestone consumption for the production of soda ash.

(b) Includes magnesite, barium carbonate, lithium carbonate, potassium carbonate, strontium carbonate and sodium bicarbonate.

Soda Ash Consumption

A tier 2 method is utilised for the Australian inventory. CO₂ emissions are associated with the use of soda ash where it is assumed that for each mole of soda ash use, one mole of CO₂ is emitted. The mass of CO₂ emitted from the use of soda ash E may be estimated from a consideration of the consumption data A_{sa} and the stoichiometry of the chemical process (where 44.01 is the molecular weight of CO₂ and 105.99 is the molecular weight of Na₂CO₃).

$$E_{\text{sa}} = 0.415 \text{ kg/tonne Na}_2\text{CO}_3 \cdot \Sigma A_{\text{sa}}$$

Data on soda ash consumption were collected under the NGER Scheme for 2009 onwards and the reporting mechanisms of the former EITEs Program for 2007 and 2008. Data for soda ash consumption for the period 1990–2006 were obtained by industry survey (Energreen 2009) and data on soda ash imports taken from ABS 2015.

Table 4.7 Soda ash use and emissions

Year	Soda ash use (kt)	Emissions (Gg CO ₂)
1990	450	187
2010	380	158
2011	361	150
2012	353	146
2013	340	141
2014	317	131
2015	271	113
2016	300	124
2017	277	115
2018	320	133
2019	332	138
2020	262	109

Source: EnerGreen Consulting 2009, NGER Scheme 2009 to date.

4.3.5 Uncertainties and time series consistency

The tier 1 uncertainty analysis in Annex 2 provides estimates of uncertainty according to IPCC source category and gas.

Time series consistency for all sources has been maintained in accordance with the principles established in section 1.4.1.

Activity data obtained under the NGER (2009–onwards) System was compared with activity data obtained from the former EITEs Program for each facility and with data obtained from GHD and Energreen consulting to ensure the consistent classification of sources and consistency of data.

Where facilities were newly identified from NGER (2009–onwards) System data as emitting facilities, in category 2.A.4, activity data was interpolated to the facility's commencement date – assuming that consumption of limestone and dolomite in previous years was equal to the consumption of limestone and dolomite in 2009 for the each of the new facilities.

Where facility-specific EFs were identified from NGER (2009–onwards) System data for particular facilities, in category 2.A.2 and 2.A.4, the observed EFs were interpolated using a national weighted average EF for all years 1990–2006.

4.3.6 Source specific QA/QC

This source category is covered by the general QA/QC of the greenhouse gas inventory in Chapter 1. Additional source specific quality control checks were undertaken to assess completeness and international comparability.

In order to maintain continuity in the compilation of *industrial processes and product use* emissions estimates, the Department engaged the external consultant previously used to collect activity data and EF information to undertake a quality control assessment of the full time series of activity data, EFs and emissions estimates. This work is of particular importance in industrial processes where confidentiality of historical activity data poses some challenges for the assessment of time series consistency.

Reconciliation between sources of carbonate supply and use in the Australian economy are undertaken to ensure completeness (see Table 4.8). This reconciliation includes limestone used in soda ash production as well as consideration of dolomite, soda ash use, magnesite and other carbonates (barium, lithium, potassium, strontium and sodium bicarbonate).

Table 4.8 Reconciliation of limestone, dolomite, soda ash, magnesite and other carbonates supply and use in the Australian economy, 2020

		Raw material ^(d) (kt)	Emissions (Gg CO ₂)	Carbon (kt)
Use				
2.A.1	Cement production	6,387	2,820	770
2.A.2	Lime production	2,351	1,056	288
2.A.3	Glass Production	176	78	21

(b) ABS 2020.

(c) Cement emissions excluding those from the calcination of magnesium carbonates.

(d) Includes tonnes of limestone, dolomite, soda ash, magnesite and other carbonates.

Comparisons of IEFs and activity data with international data sources are conducted systematically for the Australian inventory.

Figure 4.2 Cement production implied emission factors for Annex I countries (2019 Inventory) and Australia (2020 Inventory)

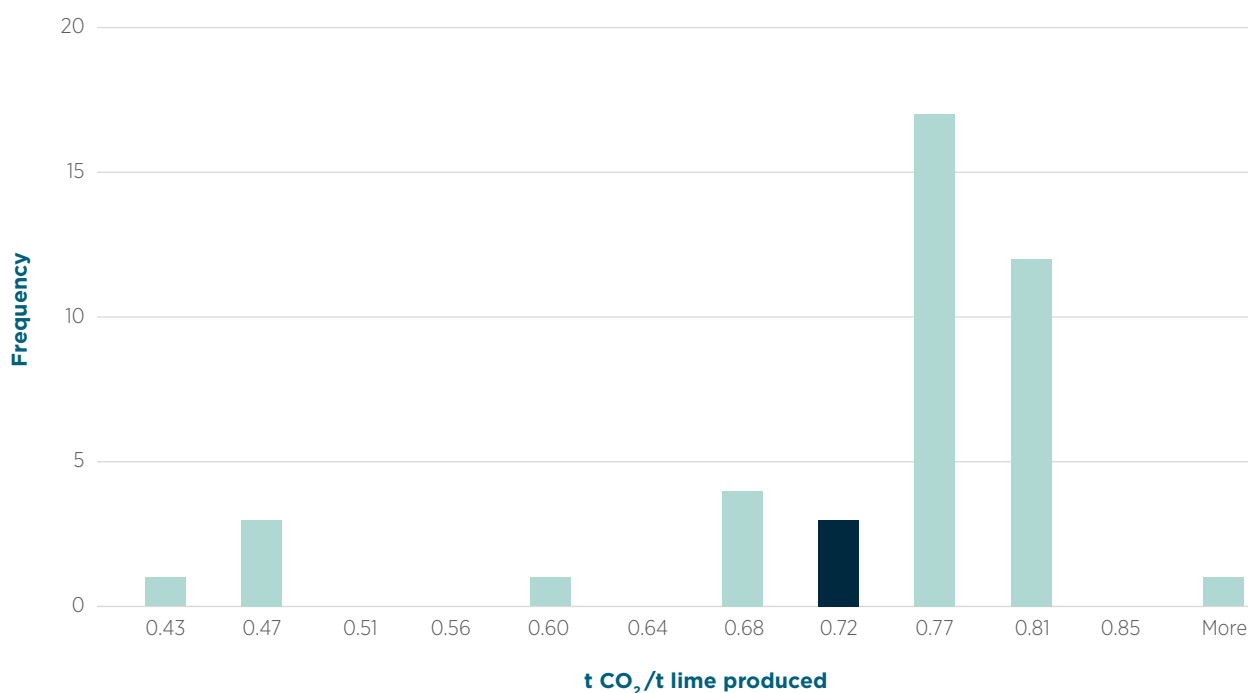

Note: In the figure above, Australia's IEF is located within the marked range.

Australia's IEF for cement production at the national level ranges between 0.54 t CO₂/tonne of cement produced and 0.56 t CO₂/tonne of cement produced. The IEF fluctuates year on year according to the relative contributions of product from each facility with their own particular product specifications. The IEF for 2020 is 0.54 t CO₂/t cement produced.

Statistical analysis indicates that the IEF for cement clinker production for Australia (included in the shaded column above) is not significantly different to the factors reported by other Annex I parties. Australia's IEF is higher than the IPCC 2006 tier 1 default EF of 0.52 t CO₂/t cement clinker produced. This is due to the relative proportions of CaO and MgO in Australia's cement clinker and the incorporation of emissions from CKD recirculation in Australia's IEF.

Figure 4.3 Lime production implied emission factors for Annex I countries (2019 Inventory) and Australia (2020 Inventory)

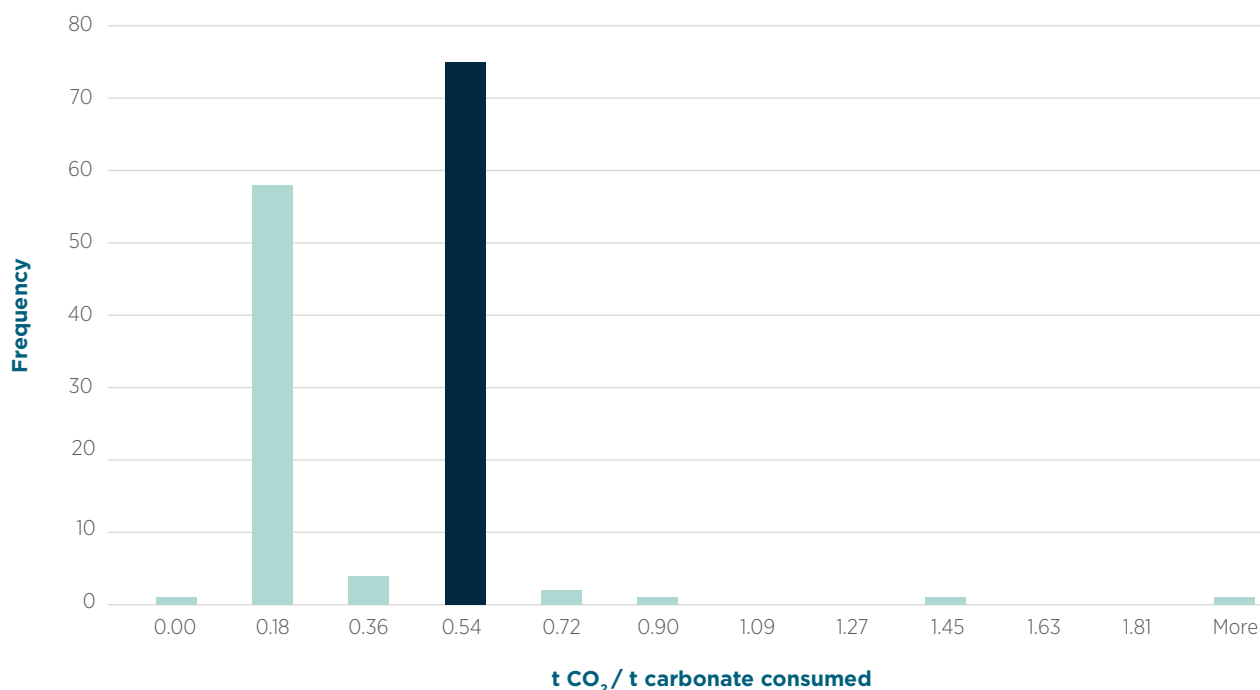

Note: In the figure above, Australia's IEF is located within the marked range.

Australia's IEF for lime production at the national level ranges between 0.68 t CO₂/tonne of lime produced and 0.82 t CO₂/tonne of lime produced. The IEF fluctuates year on year according to the relative contributions of product from each facility with their own particular product specifications reflecting the use of different types of carbonates as well as the relative proportions of commercial and in-house lime produced and lime kiln dust recirculation. The IEF for 2020 is 0.69 t CO₂/t lime produced and reflects relatively low levels of LKD calcination reported under the NGER Scheme.

Statistical analysis indicates that the IEF for lime production for Australia (included in the light shaded column above) is not significantly different to the factors reported by other Annex I parties. Australia's IEF is lower than the IPCC2006 tier 1 default EF of 0.75 t CO₂/t high calcium quicklime produced. This is due to a lower fractional purity compared with the IPCC (0.86 compared with 0.95) and the incorporation of a portion of dolomitic lime production in the default EF. In years where dolomitic lime production is reported, Australia's IEF is similar or higher than the IPCC default EF.

The IEF for *Other Process Uses of Carbonates* (2.A.4) for Australia is also reported with the distribution of IEF values for other Annex I countries. Results are shown in Figure 4.4.

Figure 4.4 Other Process Uses of Carbonates implied emission factors for Annex I countries (2019 Inventory) and Australia (2020 Inventory)

Note: In the figure above, Australia's IEF is located within the marked range.

Australia's carbonates IEF ranges between 0.410 t CO₂/t carbonate consumed and 0.490 t CO₂/t carbonate consumed. With the availability of facility level data, the national IEF fluctuates according to changes in the relative proportions of each carbonate consumed by individual facilities from year on year.

Statistical analysis indicates that the IEF for carbonates use for Australia (included in the dark shaded column above) is not significantly different to the factors reported by other Annex I parties. Australia's IEF for 2020 is 0.430 CO₂/t which is within the range of IPCC default EFs 0.380 t CO₂/t carbonate and 0.521 t CO₂/t carbonate. The 2006 IPCC Guidelines suggest the use of a fractional purity of 1 in the absence of country-specific information. In Australia's case, fractional purities of 0.9 for limestone and 0.95 for dolomite are used.

International comparison of mineral products activity data is also undertaken. Reported cement production is consistent with cement production for Australia reported by the United Nations given the high level of use of supplementary cementitious materials (fly ash and granulated blast furnace slag) in Australian cement.

The *Mineral Industry* sector was reviewed independently by an international expert (Tsaranu) in 2007. The review was undertaken applying the same principles governing regular UNFCCC inventory desktop reviews. A number of minor refinements were made to the Mineral Industry chapter in response to recommendations made in this review.

4.3.7 Recalculations since the 2019 Inventory

No recalculations were undertaken in the Minerals Products sector in this submission as set out in Table 4.9, 4.10 and 4.11.

(a) Includes 2.B.7 soda ash production

4.3.8 Planned improvements

The methodology and emission factors used for the estimation of emissions from *mineral products* will be kept under review.

Australia has been monitoring the progress of empirical research into various forms of mineral carbonation such as that associated with cement. Australia will explore the possibility of including allowance for this chemical process in future inventory submissions.

4.4 Source Category 2.B Chemical Industry

4.4.1 Ammonia production (2.B.1)

Source category description

The overall process of producing ammonia involves a series of stages to remove impurities such as sulphur, carbon monoxide, carbon dioxide and water from the natural gas feedstock and the generation and reaction of hydrogen and nitrogen. The multi stage process involved in ammonia production (from natural gas feedstock) results in the industrial process emissions of CO₂, NMVOC, and CO in addition to ammonia and sulphur compounds.

Carbon dioxide emissions from ammonia reflect the use of natural gas for both energy and feedstock uses. In Australia's inventory, only emissions from the use of natural gas as a feedstock are reported in the *industrial processes and product use* sector. An appropriate deduction has been made in natural gas consumption in the *stationary energy* sector to remove the possibility of double-counting.

A portion of carbon dioxide emissions arising from the production of ammonia are principally recovered for use in the production of urea and food and drink products. Emissions from the production and use of urea are reported under *3.H Urea Application*. Emissions from the use of carbon dioxide derived from ammonia production in the food and drink industry are reported under *2.D.2 food and drink*.

Ammonia is produced in seven plants operated by six producers in Australia; Incitec, Orica, Wesfarmers, BHP-Billiton, Queensland Nitrates and Burrup fertilisers. All companies provided natural gas consumption and CO₂ recovery data (where appropriate) for this Inventory under the NGER Scheme.

Methodology

A tier 1b method is utilised for the Australian inventory. Ammonia is manufactured by the catalytic steam reforming of natural gas. Hydrogen from the reformed natural gas and nitrogen from air are compressed at reduced temperatures to form ammonia:

The overall manufacturing process for ammonia production involves a series of stages to remove impurities such as sulphur, carbon monoxide, carbon dioxide and water from the natural gas feedstock and the generation and reaction of hydrogen and nitrogen.

The manufacture of ammonia from the catalytic steam reforming of natural gas is documented to result in emissions of CO₂, NMVOC and CO. While the CO₂ equivalent emissions associated with the use of natural gas are accounted for, data on emissions of NMVOC and CO are not currently available. It is assumed that carbon in natural gas feedstock is converted entirely to CO₂.

The general method for deriving emissions relates a country-specific emission factor EF, (reported in Table 3.2) to plant specific natural gas consumption data Ai:

$$E_a = \sum A_i \cdot EF_i - R$$

R is CO₂ captured and sold for use in the food and drink industry and urea production. Carbon dioxide is captured and used in either the production of urea or the manufacture of food and drink products. The CO₂ recovered for use in urea production is deducted from CO₂ emissions from ammonia production and CO₂ emissions associated with the consumption of urea on agricultural land is reported under *3.H Urea Application*.

The quantity of CO₂ recovered for use in food and drink applications is derived from data reported under the NGER Scheme. Ammonia producers are required to report the quantity of CO₂ recovered and used in urea production and it is assumed that CO₂ recovered and not used in urea production is sold to the food and drink industry. Emissions associated with CO₂ use in the food and drink industry are reported under *2.H Other*.

Choice of emission factor

A facility-specific EF for the consumption of natural gas for five facilities reported under the NGER Scheme were used for 2009 onwards where available. In 2020, one facility reported a facility specific emissions factor.

For the remaining three facilities, no facility-specific EF information was available. Therefore the country-specific EF for the consumption of natural gas as listed in Table 3.2 of the NIR was used.

Emissions estimates for ammonia production for all facilities (including the facility reporting a facility-specific emission factor) assume 100 per cent oxidation of natural gas takes place in line with GPG recommendations.

Facility specific emission factors for overall ammonia production plants are not available directly through the NGER Scheme. However, these can be inferred from reported data and the average implied emission factor for CO₂ from generated Australian ammonia production plants was 1.34 tonnes CO₂/ tonne NH₃ in 2020. This IEF is 6.6% lower than for 2019. However, throughout the time series there is some greater volatility in inter annual IEF variations caused by some facilities not reporting facility specific EF in conjunction with natural gas consumption and ammonia production.

This value is lower than the 2.1 tonnes CO₂ / tonne NH₃ IPCC default European average value, reflecting modern practices in Australian ammonia production. Facility specific EFs are confidential.

Activity data

Data on fuel consumption, ammonia production and CO₂ capture were obtained under the NGER Scheme for 2009 onwards. Data for consumption of fuels were derived from data on production for the period 1990–2008 provided by Energreen 2009 and constant consumption to production factors in order to ensure time series consistency. Complete coverage of all ammonia producers has been maintained through the data collection mechanisms utilised throughout the time-series as listed above.

In response to an ERT recommendation, it was identified that one facility had reported production combined with imports for the years 2012–2017, rendering actual production data for the facility uncertain. Australia will continue to source accurate data, however in the meantime Australia has indexed production data for these years based accurate production and IEF for 2019.

Production and emissions from ammonia production are shown in Table 4.12.

Table 4.12 Production and emissions from the production of ammonia 1990, 2000–2020

	Production (kt)	Emissions (Gg CO ₂ -e)

2020	1,816	2,135

Source: Energreen 2009, NGER 2009 Onwards. DISER 2020.

4.4.2 Nitric acid production (2.B.2)

Source category description

The manufacture of nitric acid (HNO₃) generates N₂O as a by-product of the high temperature catalytic oxidation of ammonia (NH₃). Nitric acid is used as a raw material mainly in the manufacture of nitrogenous agricultural fertiliser.

Nitric acid is produced by three producers in Australia; Wesfarmers, Orica and Queensland Nitrates.

Emissions for the nitric acid category are reported as 'included elsewhere' where the estimates are aggregated with emissions from the use of N₂O in anaesthesia and aerosols and included under *2.B.6 confidential chemical industry emissions*.

Methodology

A tier 3 method is utilised for the Australian inventory. Nitric acid production involves three distinct chemical reactions. These are summarised as follows:

Nitric oxide (NO), an intermediate in the manufacture of nitric acid, is documented to readily decompose to N₂O and nitrogen dioxide (NO₂) at high pressures for temperatures in the range of 30 to 50°C.

Facility-specific EFs for N₂O from nitric acid production EF_n are based on periodic measurements of the off-gas emitted at nitric acid production plants in the Australia. These EFs are confidential.

The emissions of N₂O, E_n, from the manufacture of nitric acid production A_n is calculated according to:

$$E_n = A_n \cdot EF_n$$

Choice of emission factor

The selection of EFs was undertaken in accordance with the decision tree in section 1.4.1.

The EFs for nitric acid production are facility-specific and obtained under the NGER Scheme for 2009 onwards. The majority of nitric acid production plants apply NGER method 4, which prescribes periodic or continuous measurement. Other facilities applied NGER method 2, which prescribes periodic updated EFs.

Individual plant specific emission factors reported under the NGER Scheme are not provided due to confidentiality constraints.

For earlier years, incomplete data on facility-specific EFs were available from Energreen 2009. Where facility-specific factors were not available, no information about the factors applicable to the remaining facilities were inferred from the Energreen data on the assumption that factors applicable to each facility are technology-specific and independent of each other. In these cases, IPCC good practice default factors were applied in accordance with information available on the applicable technologies (Energreen 2009).

Time series consistency is maintained by the interpolation of the available facility-specific EFs to the most recent year for which data were available.

Activity data

Data on nitric acid production for individual facilities were collected under the NGER Scheme from 2009 onwards.

Data for nitric acid production for the period 1990–2008 were provided by Energreen 2009.

Complete coverage of all nitric acid producers has been maintained through the data collection mechanisms utilised throughout the time-series as listed above.

NGER methods provide reporters methods for reporting plant specific variables such as emission factors. Consistent with IPCC 2006, NGER methods are able to account for operational conditions during a reporting year such as temporary losses of N₂O destruction capability.

Production and emissions from nitric acid production are shown in Table 4.13.

Table 4.13 Production and emissions from the production of Nitric Acid (including medical N₂O use)

	Production (kt)	N ₂ O Emissions (Gg CO ₂ -e)
1990	297	995
2000	536	1,734
2001	657	2,083
2002	713	2,213
2003	748	2,490
2004	756	2,462
2005	858	2,660
2006	915	2,624
2007	992	2,740
2008	1,082	3,092
2009	1,222	2,997
2010	1,286	3,134
2011	1,269	2,550

2019	1,699	2,228
2020	1,815	1,947

Source: Energreen 2009, NGER 2009 Onwards

4.4.3 Adipic acid production (2.B.3)

There is no adipic acid production occurring in Australia.

4.4.4 Caprolactum, glyoxal and glyoxix acid production (2.B.4)

There is no Caprolactum, Glyoxal and Glyoxix Acid production occurring in Australia.

4.4.5 Carbide production (2.B.5)

Silicon carbide and calcium carbide are not produced in Australia. Minor quantities of acetylene are produced from imported calcium carbide and used in welding applications. Data are reported by one company, BOC. Emissions for this category are reported as 'included elsewhere' where the estimates have been aggregated with emissions from *soda ash production* included in 2.B.10 *confidential chemical industry emissions*.

4.4.6 Other (2.B.6) Titanium dioxide production

Source category description

Rutile (titanium dioxide) is naturally occurring in Australia. Synthetic rutile can be produced from naturally occurring ilmenite using coal reductant. The rutile is then refined using petroleum coke reductant to produce titanium dioxide (TiO₂).

Titanium dioxide is a white pigment which is used in paint manufacture, paper, plastics, rubber, ceramics, fabrics, floor covering, printing ink, and other miscellaneous uses). Titanium dioxide products are referred to generically as titanium dioxide unless there is a need to make a distinction between the products.

Synthetic rutile is produced in Australia by Iluka Resources and Tiwest whilst TiO₂ is produced by Tiwest and Millennium Chemicals.

The use of coal and petroleum coke as reductants in the synthetic rutile and TiO₂ production processes are accounted for in the *industrial processes and product use* sectors. These reductant quantities have been removed from the stationary energy sector to eliminate the possibility of a double-count.

Methodology

A tier 2 method is utilised for the Australian inventory. The processes that are used in the production of TiO₂ in Australia that lead to process greenhouse gas emissions are synthetic rutile production using the Becher process, and rutile TiO₂ production via the chloride route.

The Becher process reduces the iron oxide in ilmenite to metallic iron and then reoxidises it to iron oxide, and in the process separates out the titanium dioxide as synthetic rutile of about 91 per cent to 93 per cent purity. Rutile TiO₂ is produced through the carbothermal chlorination of rutile ore or synthetic rutile to produce titanium tetrachloride (TiCl₄) and oxidation of the TiCl₄ vapours to TiO₂ according to the following reactions (Kirk-Othmer, 1999; p.2018):

Based on stoichiometry and assuming complete conversion of the input C to CO₂ through further conversion of CO in excess air, the CO₂ EF cannot be less than 0.826 tonnes of CO₂ per tonne of TiO₂ (based on 1.5 moles of CO₂ per mole of TiO₂).

Emissions from rutile and TiO₂ respectively may be calculated by:

$$\text{CO}_2 \text{ Emissions} = \sum \text{EF}_i \cdot A_i$$

Where EF_i is the EF for fuel type i and A_i is the quantity of fuel type i consumed as a reductant

Choice of emission factor

No facility-specific information on EFs from the NGER Scheme has been used in this inventory. Country-specific EFs are applied to the quantities of black coal and petroleum coke consumed in the synthetic rutile and titanium dioxide production processes.

Activity data

Data on synthetic rutile and TiO₂ production, black coal and petroleum coke consumption were obtained under the NGER Scheme from the three manufacturers, Illuka, Tronox and Cristal. For the inventory years 2007 and 2008, activity data collected under the former EITEIs Program has been used.

Data for consumption of coal and petroleum coke were derived from data on production for the period 1990–2006 provided by Energreen 2009 and constant consumption to production factors in order to ensure time series consistency.

Complete coverage of all synthetic rutile and titanium dioxide producers has been maintained through the data collection mechanisms utilised throughout the time-series as listed above.

Aggregated emissions from *synthetic rutile production* and *titanium dioxide production* are shown in Table 4.14.

Table 4.14 Aggregated emissions from the production of synthetic rutile and TiO₂

4.4.7 Soda ash production (2.B.7)

Source category description

A tier 3 method is utilised for the Australian inventory. Soda ash (sodium carbonate, Na₂CO₃) is used as a raw material in a large number of industries including glass manufacture, soap and detergents, pulp and paper manufacture and water treatment.

The majority of soda ash was produced by one company, Penrice Soda Products, located in South Australia, using the Solvay process. This production has now ceased and the facility converted for import and distribution. The majority of soda ash consumed in Australia is now imported primarily from the United States of America. There remains one company in Australia producing soda ash for its own in house use.

The method is described below for completeness and to describe the estimation of historical emissions associated with Soda Ash production in Australia,

Emissions of CO₂ are generated from both the consumption and production of soda ash. To protect confidentiality, these emissions are aggregated with emissions from *acetylene* under 2.B.10.

Emissions from the production of soda ash include emissions from the coke used as a reductant. This quantity of coke is deducted from the energy sector as it is a non-energy use of coke and ensures there is no double-counting. Limestone is also consumed in the manufacture of soda ash and both the emissions from the calcination of limestone and the coke used as a reductant are accounted for under *Chemical Industry* (2.B).

Sodium bicarbonate (NaHCO₃) is also produced in the Solvay process for soda ash production. When heated or reacted with a weak acid, sodium bicarbonate generates CO₂.

Emissions from the use of sodium bicarbonate in applications where CO₂ is generated have been included in the inventory under Food and Beverages Industry (2.H.2). CO₂ emissions for this sector are derived as a function of sodium bicarbonate supplied to the economy and a known proportion being used for emissive purposes.

Methodology

Soda Ash Production

In the Solvay process, sodium chloride brine, limestone, coke and ammonia are the raw materials in a series of reactions leading to the production of soda ash, sodium bicarbonate and waste products containing calcium carbonate. Ammonia, however, is recycled and only a small amount is lost.

The series of reactions involved in the Solvay process may be simply expressed as:

The CO₂ generated in pyrolysis processes is captured, and directed to Solvay precipitating towers for consumption in a mixture of brine (aqueous NaCl) and ammonia. The Solvay process itself is in theory stoichiometrically neutral in relation to CO₂ gas (that is, generation equals uptake), however, in practice a greater amount of CO₂ is generated than can be absorbed in order to optimise the production process.

Emissions from soda ash production are estimated using a tier 2 method.

The estimation of the CO₂ emissions from a standalone soda ash plant should be based on an overall balance of CO₂ around the whole chemical process. To estimate the excess CO₂ generated during production the carbon in the products and waste materials is deducted from the carbon in the raw materials leaving the excess carbon which is assumed to be entirely converted to CO₂ gas.

$$E_s = [\sum_f CC_f \cdot A_f + CC_l \cdot A_l - \sum_p CC_p \cdot A_p - \sum_w CC_w \cdot A_w] \cdot 3.664$$

Where E_s is the emissions of CO₂ from the production of soda ash and sodium bicarbonate
 CC_f is the carbon content of the fuel consumed
 A_f is the mass of fuel consumed (coke)
 CC_l is the carbon content of the limestone consumed

- A_f is the mass of limestone consumed
- CC_i is the carbon content of a product
- A_p is the mass of product (soda ash and sodium bicarbonate)
- CC_w is the carbon content of the waste products
- A_w is the mass of waste product (brine mud)

In the first step of the Solvay process limestone is calcined to form lime which is then mixed with water to produce slaked lime for the ammonia recovery step. Any limestone that is not calcined is removed as waste (backstone and grits) from the process and this is deducted from the mass of limestone consumed A in the emissions estimate.

A relatively small amount of waste material containing carbon in the form of calcium carbonate is also deducted from the carbon in the raw materials. The calcium carbonate waste is produced during a brine purification process where calcium and magnesium salts are removed from the brine feedstock. The purification of the brine is achieved through a reaction of soda ash and sodium hydroxide with the calcium and magnesium salts in the brine forming the solids, calcium carbonate and magnesium hydroxide. Calcium carbonate is also formed in the manufacture of the sodium hydroxide used in these reactions.

Soda ash is taken from the product stream and diverted to the brine purification process where it reacts with the calcium salts (calcium sulphate) to form calcium carbonate and sodium sulphate:

Sodium hydroxide is manufactured using soda ash (also diverted from the product stream) and slaked lime with calcium carbonate as a waste by-product:

The sodium hydroxide manufactured is then fed into the brine purification process where it reacts with the magnesium salts (magnesium sulphate) to form magnesium hydroxide and sodium sulphate.

In this way the CO_2 absorbed into the soda ash product is then diverted for use in the brine purification process and the manufacture of sodium hydroxide is converted into calcium carbonate. The carbon in the calcium carbonate formed in these reactions is deducted from the raw materials in the calculation of the emissions estimate. The soda ash product used in the brine purification process and manufacture of sodium hydroxide is essentially a non-emissive use of soda ash and the amount used is not included in the total soda ash produced for sale.

Sodium Bicarbonate Consumption

Sodium bicarbonate (NaHCO_3) is also produced in the manufacture of soda ash using the Solvay process. Sodium bicarbonate has a wide range of applications some of which result in the release of CO_2 . When sodium bicarbonate is heated or reacted with a weak acid CO_2 is released. Uses of sodium bicarbonate in which CO_2 is generated include leavening agents, pharmaceuticals, stock feed buffer and effervescent salts and beverages.

Energreen Consulting 2009 indicates that the proportion of sodium bicarbonate consumption resulting in emissions of CO_2 is 80 per cent. This proportion is used to estimate the amount of CO_2 emissions from consumption of sodium bicarbonate. It is assumed that the sodium bicarbonate thermally decomposes in the following reaction:

The mass of CO₂ emitted from the use of sodium bicarbonate Esbu is estimated using consumption data Asbu, the proportion resulting in emissions and the stoichiometry of the chemical process (where 44.01 is the molecular weight of CO₂ and 84.01 is the molecular weight of NaHCO₃).

$$E_{\text{sbu}} = 0.8 \cdot A_{\text{sbu}} \cdot 0.262 \text{ kg/tonne NaHCO}_3$$

Choice of emission factor

Soda Ash Production

The selection of EFs was undertaken in accordance with the decision tree in section 1.4.1.

The EFs for limestone consumption and coke consumption are facility-specific and obtained under NGER for 2009 onwards and under the former EITEIs Program for 2007 and 2008. As there is only one producer, complete coverage for the sector was achieved.

Time series consistency for the entire period 1990–2006 is maintained by the application of the facility-specific factors, obtained for the period 2007–2008, to years when no facility data are available.

Activity data

Soda Ash Production

Data on limestone and coke consumption for the purpose of soda ash production were collected under the NGER System for 2009 onwards and the reporting mechanisms of the former EITEIs Program for 2007 and 2008.

Data for limestone and coke consumption for the period 1990–2006 were derived from data for soda ash production obtained by industry survey (Energreen 2009). Time series consistency was maintained by the application of constant factors of limestone and coke consumption per unit of soda ash production estimated from data available for the period 2007–2009.

4.4.8 Petrochemical and carbon black production (2.B.8)

Source category description

The manufacture of organic chemicals results in process emissions of NMVOC. Other gases such as CO₂, CH₄, N₂O, NO_x and CO may also be generated depending on the manufacturing process.

Complete time series of emissions of CH₄ and NMVOCs are included in the inventory for methanol, butadiene, carbon black, ethyl benzene, ethylene, ethylene oxide, formaldehyde, HDPE, LDPE, LLDPE, propylene, polypropylene, polystyrene, styrene, polyvinyl chloride, and styrene butadiene rubber. Disaggregated production and emissions data for these sources are confidential. Emissions estimates are aggregated at the polymers and other chemicals source category level.

There are approximately 15 companies producing a large range of polymers and other chemicals in Australia. Companies include Dynea W.A, Borden Chemicals, Orica, BP, Shell, Huntsman Chemicals, Dow Chemicals, Genos, ExxonMobil, Continental Carbon, Koppers, Australian Vinyl, BOC Gases, Airliquide, Caltex, and Nuplex.

Methanol was produced by one plant owned by Coogee Chemicals which has been operating since 1994 with an annual production capacity of 80 kt (see Coogee Chemicals website <http://www.coogee.com.au>). Due to the inability to secure competitively priced natural gas in Victoria with prices exceeding AUD\$10/GJ, the plant was placed in care & maintenance mode in March 2016.

Methanol production was undertaken by one plant in Australia, which has since suspended operation. Dichloroethylene is used to produce vinyl chloride monomer (VCM) which is used to produce polyvinyl chloride (PVC) resin. All PVC resin manufactured in Australia is produced from imported VCM. (<https://vinyl.org.au/about-vinyl/manufacturing-process>). Dichloroethylene production does not occur in Australia.

CO₂ emissions from ethylene oxide production are reported in 2.H Food and Drink, where by product CO₂ is used and emitted.

Methodology

A tier 2 method is utilised for the Australian inventory, incorporating emission factors derived from plant specific data (EnerGreen 2009). Emissions from miscellaneous organic chemical manufacture are dependent on the level of activity and extent of emission control and estimated according to equation:

$$E_{ij} = (A_j \times EF_{ij})/10^6$$

Where E_{ij} is the process emission (Gg per year) of gas i from industrial sub-sector j
 A_j is the amount of activity (production or consumption) of material in industrial sector j (tonnes per year unless)
 EF_{ij} is the EF associated with gas i per unit of activity in industrial sector j (kg per tonne) – see Table 4.15
The divisor 10^6 is a factor for converting kg to Gg (kt) (1,000,000kg = 1 Gg)

Australia was not able to identify a CO₂ EF unique to the technology type previously used in Australia, and does not have feedstock consumption data available to support a mass balance equation. As an alternative, it was identified the CH₄ IEF for Methanol production in the USA is similar to Australia (2.3 kg/t vs 2.0 kg/t for Australia) – as this implies a comparable production technology in used, Australia derived CO₂ emissions using the USA CO₂ IEF of 670 kg/t.

Table 4.15 Emission factors for organic chemicals

Subsector	CO ₂ (kg/tonne)	CH ₄ (kg/tonne)	NM VOC (kg/tonne)
Acetylene ^(a)	3 384 kg CO ₂ per tonne C ₂ H ₂ used		
Butadiene			1.5
Carbon black		0.11	0.5
Ethyl benzene			0.03
Ethylene		0.03	0.25-1.5
Ethylene oxide			0.069
Formaldehyde			9.2
HDPE			1.5
LDPE and LLDPE			1.5
Methanol ^(b)	670 ^(c)	0.002	
Propylene			1.5
Polypropylene			1.5
Polystyrene ^(b)			0.1-5.4
Styrene ^(b)		4	18
Styrene butadiene rubber		1.5	1.5
Polyvinyl chloride		8.5	8.5

Source: EnerGreen 2009. (a) Based on stoichiometry. (b) IPCC 1997. (c) USEPA 2021.

4.4.9 Uncertainties and time series consistency

The tier 1 uncertainty analysis in Annex 7 provides estimates of uncertainty according to IPCC source category and gas.

Activity data obtained under NGER was compared with activity data obtained from the former EITEIs Program for each facility and with data obtained from GHD and Energreen consulting to ensure the consistent classification of sources and consistency of data.

No facilities were newly identified from NGER data as emitting facilities for this category.

Where facility-specific EFs were identified from NGER data for particular facilities, in category 2.B.2, the reported EFs for 2007, 2008 and 2009 were interpolated for each facility to the most recent year for which data were available.

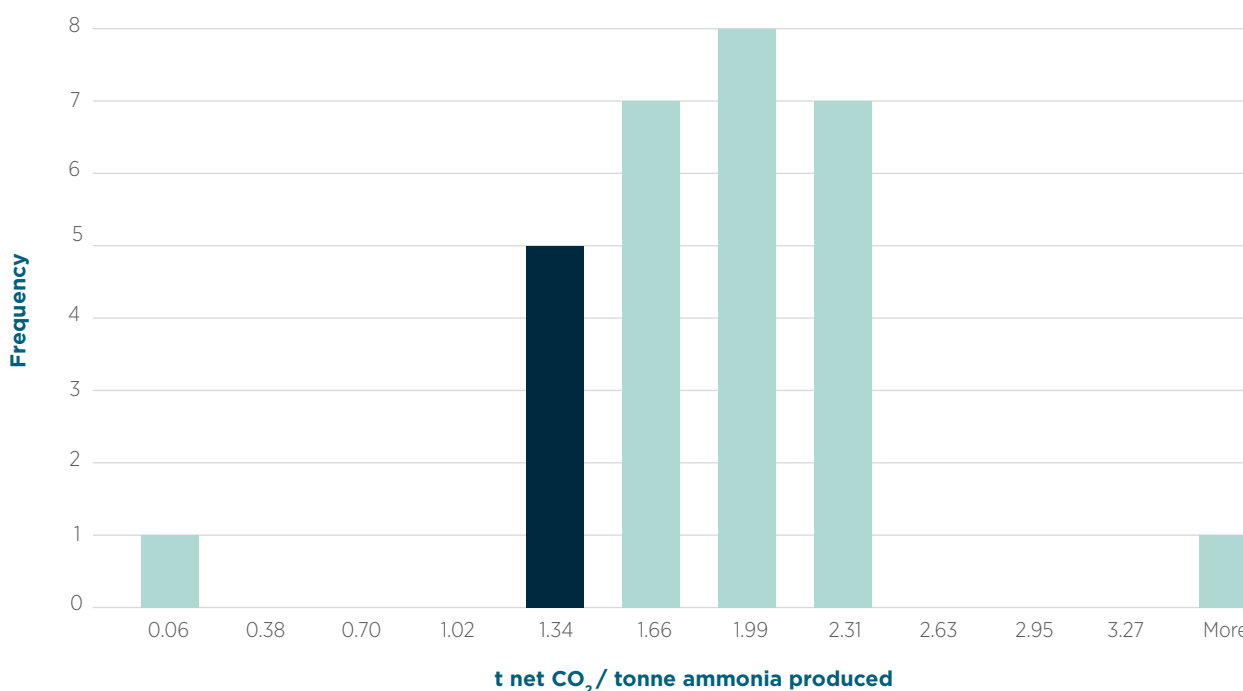

4.4.10 Source specific QA/QC

This source category is covered by the general QA/QC of the greenhouse gas inventory in Chapter 1. Additional source specific quality control checks were undertaken to assess international comparability.

The IEF per unit of production for Australia's inventory was compared with the IEFs for other Annex I parties in the cases of ammonia and nitric acid production. The factors for Australia were found to be not significantly different to the factors reported by other Annex I parties. The results of this comparison are presented below.

The quantity of CO₂ generated per tonne of ammonia produced has been compared with that of Annex I parties reporting emissions from ammonia production. The results of this comparison are shown in Figure 4.5.

Figure 4.5 Ammonia implied emission factors for Annex I countries (2019 Inventory) and Australia (2020 Inventory)

Note: In the figure above, Australia's IEF is located within the marked range.

The IEF for ammonia production for Australia ranges between 1.060 t CO₂ generated per tonne of ammonia produced and 1.552 t CO₂ generated per tonne of ammonia produced. The IEF fluctuates year on year according to fluctuations in ammonia production levels of individual facilities.

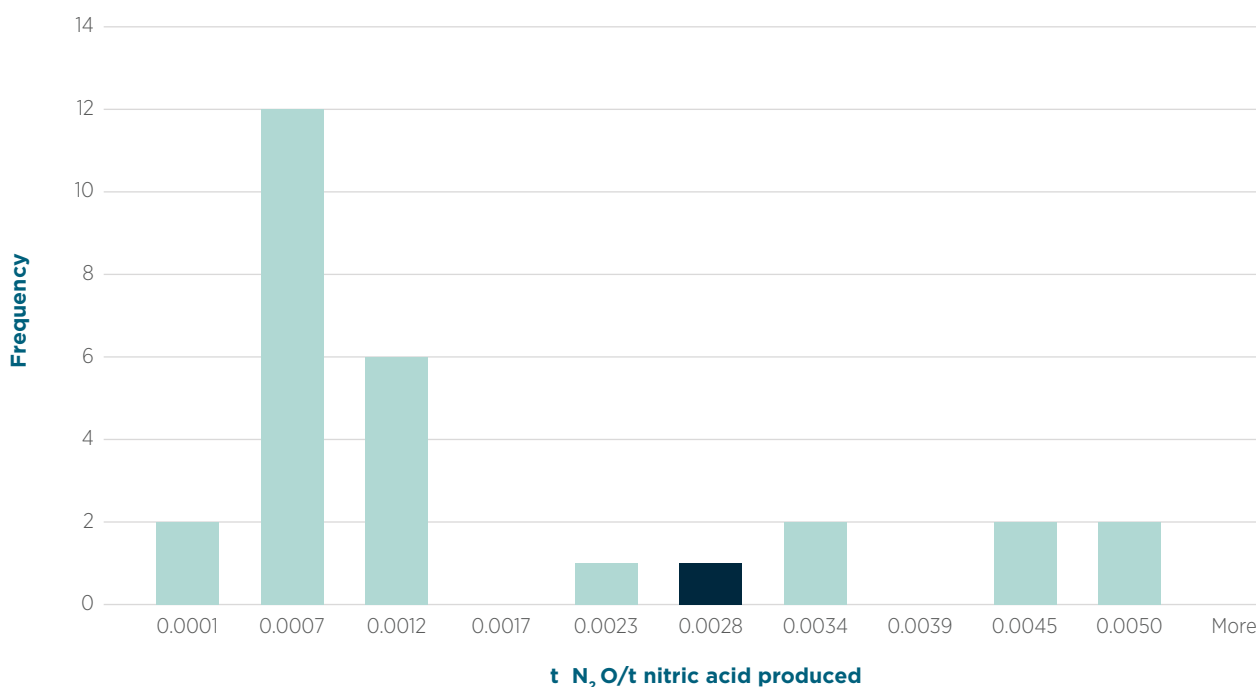

In general, Australia's IEF is generally lower than the default values listed in the *2006 IPCC Guidelines* of 1.666–3.273 t CO₂/t ammonia. The *2006 IPCC Guidelines* lists a range of default “total fuel requirements” (including natural gas consumed for energy purposes as well as chemical feedstock) by production process ranging between 29.7 GJ fuel/t NH₃ and 42.5 GJ fuel/t NH₃. Under the NGER Scheme, Australian ammonia facilities must report feedstock and fuel use separately and it is only the feedstock quantity that is used in the estimation of CO₂ emissions. Australia's feedstock fuel requirements range between 21.04 and 30.16 GJ fuel/t NH₃ produced.

This specific IP / non-IP split in activity data explains the difference between Australia's IEF and the IPCC defaults. The specific ammonia production technology mix in Australia will also cause differences between parties and the default IPCC values.

Statistical analysis indicates that the IEF for ammonia production for Australia is not significantly different to the factors reported by other Annex I parties.

The quantity of N₂O emitted per tonne of nitric acid produced has also been compared with that for Annex I parties. The results of this comparison are shown in Figure 4.6.

Figure 4.6 Nitric acid implied emission factors for Annex I countries (2019 Inventory) and Australia (2020 Inventory)

Note: In the figure above, Australia's IEF is located within the marked range.

The IEF for nitric acid production for Australia ranges between 0.002 t N₂O per tonne of nitric acid produced and 0.01 t N₂O per tonne of nitric acid produced. The IEF fluctuates year on year according to fluctuations in nitric acid production levels at individual facilities. Emissions at individual facilities are highly technology-specific with three main types of production plants and differing levels of abatement technology in place.

Statistical analysis indicates that the IEF for nitric acid production for Australia is not significantly different to the factors reported by other Annex I parties.

In 2011, the Department engaged a consultant to review N₂O emissions control in the nitric acid industry (EnerGreen Consulting 2011). This review found that a number of facilities were either trialling N₂O emissions reduction technology or monitoring developments domestically and internationally with a view to retrofitting existing plants or integrating abatement technology into future expansions.

Plant-level EFs have been declining since 1990 and more recent reductions have come about as a result of the introduction of continuous monitoring of N₂O emissions and an associated improvement in management of process catalysts.

The *chemical products* category was reviewed independently by an international expert (Tsaranu) in 2007.

The review was undertaken applying the same principles governing regular UNFCCC inventory desktop reviews. A number of minor refinements were made to the chemical products chapter in response to recommendations made in this review.

4.4.11 Recalculations since the 2019 Inventory

Minor revisions to N₂O use due to revised population statistics from 2009–2019.

Table 4.16 2.B Chemicals: recalculation of total CO₂-e emissions (Gg), 1990–2019

Year	2021 Submission	2022 Submission	Change	Change

4.4.12 Planned improvements

Methods and AD will be kept under review.

4.5 Source Category 2.C Metal Industry

4.5.1 Iron and steel production (2.C.1)

Source category description

Iron and Steel production is a key source in the Australian inventory. Emission sources relate to the in-house production of metallurgical coke, the use of limestone and dolomite as flux in iron, steel and ferro-alloy production and fugitive gas leaks associated with the distribution of coke oven gas and other products within industrial premises. Carbonate use is accounted for under 2.A.2.

Metallurgical coke is an essential material in iron and steel production where it serves a number of major functions including the provision of a porous support for furnace ingredients, as a combustion ingredient producing the reducing atmosphere required for ore refinement and as a chemical reductant. Since 2003, pulverised coal has also been used in Australian iron and steel production to improve the performance of the blast furnace. Emissions from the use of coke and pulverised coal as a reductant are reported in this category.

Emissions from the production of coke are reported under category 1.A.1 while the emissions generated by the combustion of coke oven gas to produce energy are reported under the stationary energy category 1.A.2. An assessment of NGER energy data confirms there is currently no consumption of blast furnace gas by any facilities external to the iron and steel facilities. Accordingly, no re-allocation of CO₂ emissions associated with that activity to the Energy sector is required. This is kept under review for changes in practice.

Iron and steel producers perform a facility level carbon balance for their integrated metal works, with all carbon inputs and emissions associated with the process accounted for. Emissions from iron and steel production in the inventory are based on the carbon inputs into the integrated production process.

In addition to process emissions reported in 2.C, emissions associated with natural gas consumption in the production of sinter are included in *1.A.2.a Iron and Steel*.

There are two major producers of iron and steel in Australia; Liberty and Blue Scope. Integrated iron and steel production occurs primarily in New South Wales and South Australia. A hot briquetted iron (HBI) plant that used natural gas as a reductant in Western Australia between 2000 and 2005 is also included in the estimates from *2.C.1 iron and steel production*. In addition to the production of iron and steel from integrated iron and steel facilities, there are also three iron and steel producing facilities where electric arc furnaces are in operation.

Emissions associated with the consumption of fuels as reductants or anode ingredients are also estimated under *2.C.1 iron and steel production*.

Emission from *iron and steel production* are reported as “included elsewhere” where estimates are aggregated with emissions from *ferroalloys production* and *other metals production*, and included under *2.C.7 other*.

Methodology

A tier 2 method is utilised for CO₂ and tier 2 for non-CO₂ in the Australian inventory. The manufacture of iron involves the high temperature reduction of iron-bearing materials in a blast furnace. The blast furnace is essentially a large chemical reactor charged with iron ore, coke and limestone/dolomite to produce hot metal or ‘pig iron’ which is converted into steel typically by injecting oxygen gas through a charge of scrap and the molten iron. During the process, lime is added to remove impurities and provide a slag of the desired basicity.

The chemical reactions that occur in the blast furnace to produce molten iron (Fe as shown in the equations) may be summarised as follows:

Coke

The emissions from the use of coke as a reductant are estimated according to equations 3.1 and 3.2 reported in Chapter 3.

The CO₂ EF used to compile the emission estimate for coke consumption (shown in Table 4.17) is derived from a carbon mass balance calculation conducted for the coke oven process. A full time series of coke emission factors is provided in Table 3.A.23 in the NIR.

A schematic diagram of the carbon balance used to derive the coke emission factor is provided in section 3.4.2 of the NIR. This balance is performed to ensure carbon inputs into the coke oven are balanced with all known outputs. In the case of coke ovens, the input is black coal and outputs are coke oven gas, coal tar and coke.

All outputs are reported in Australia's energy statistics in the form of energy. With emission factors for black coal, coke oven gas and coal tar known, a balance is achieved through the derivation of an appropriate coke emission factor. This balance is performed each year with each new release of the *Australian Energy Statistics* (DISER 2021).

Table 4.17 Carbon dioxide emission factors for iron and steel

Fuel Type	Oxidation Factor (per cent)	Emission Factor (Gg/PJ)
Coke	100 ^(a)	109.4
Natural Gas	100	51.4 ^(c)

Notes:

- (a) IPCC (2006) default value.
- (b) IPCC (2006) default value.
- (c) The CO₂ EF for coke is derived from a carbon balance calculation conducted for the coke oven process. The natural gas EF is provided by the Australian Gas Association.

Table 4.18 Non-carbon dioxide emission factors for iron and steel

Fuel Type	Emission Factors (Mg/PJ)					
	CH ₄	N ₂ O	CO	NO _x	NMVOC	SO ₂
Coke	0.95	0.71	91.25	190.99	0.86	370
Natural Gas	0.95	0.55	69.4	499.45	1.49	2.3

The raw steel produced contains carbon, the ultimate source of which is fossil carbon from the coal input to coke ovens. Since steel is a long-lived product, this is a form of carbon sequestration. The carbon content of steel is reported directly by iron and steel producers under the NGER Scheme. The reported carbon contents of steel across all producers between 0.16 per cent and 0.19 per cent.

Fugitive Emissions

In addition to the estimation of emissions from the use of coke and gas as reductants, a process EF is established for CH₄ from integrated iron and steel production (0.44 kg CH₄ / tonne of crude steel produced) to reflect mainly sources of fugitive emissions. The estimated CH₄ EF is based on experimental data and engineering calculations conducted at the plant owned by BlueScope Steel by BHP (pers. comm. 2000) for its major Australian integrated iron and steelworks. Process emission sources considered include the in-plant distribution of coke oven gas and natural gas, leakage from coke ovens and the bleeding of unflared blast furnace gas to the atmosphere. By comparison with fugitive emissions from the in-plant distribution of coke oven gas, emissions of CH₄ associated with leakage from coke ovens and the bleeding of unflared gas from blast furnaces are estimated to be of minor significance.

Fugitive emissions of CO₂ from blast furnace gas and other process gases are included in totals reported in the energy sector, with fugitive emissions reported for Iron and Steel production being from the distribution of natural gas (containing trace amounts of CO₂) within facilities.

Activity data

Activity data for coke consumption in the production of iron and steel are obtained from DISER *Australian Energy Statistics* (DISER 2021) for inventory years up to 2009 and the NGER Scheme from 2009 onwards. Crude steel production has been sourced directly from companies (Energreen 2009 and the NGER Scheme). Data on pulverised coal consumed in the blast furnace have been obtained from investor reports published by Bluescope Steel (Bluescope 2014). In 2009, NGER crude steel production reporting under the NGER Scheme was incomplete and was derived by indexing the crude steel production in 2008 to the changes in coke consumption in 2009. This is not the case in subsequent years where crude steel production reporting was complete.

Complete coverage of all iron and steel production has been maintained through the data collection mechanisms utilised throughout the time-series as listed above.

4.5.2 Ferroalloys production (2.C.2)

Source category description

Emissions from the consumption of fossil fuels when used as reductants, or when used to produce carbon anodes on-site, or as carbon anodes are estimated under this category. There is one company producing ferroalloys in Australia consuming black coal, coking coal, coke oven coke, petroleum coke and limestone in the process.

The availability of NGER Scheme data on reductant consumption in the production of ferroalloys has enabled reductant emissions from this source to be estimated for the first time in this submission. These emissions are reported under *2.C.7 Other Metals* to protect confidentiality of data. An equivalent deduction has been made in stationary energy to ensure there is no double counting or omission of emissions. The use of limestone in the production of ferroalloys is reported under *2.A.4 Other Process Uses of Carbonates*.

Methodology

Emissions from the consumption of reductants in the production of ferro-alloy metals have been estimated using a tier 2 method. Emissions from the use of reductants in the production of ferroalloys are estimated by the application of a country-specific EFs and the oxidation factors in section 3.4 to the quantity of each reductant used.

Choice of emission factor

EFs have been selected in accordance with the decision tree in section 1.4.1. No information on facility-specific EFs were available under the NGER Scheme. Time series consistency has been maintained by the application of values for EFs for 2009 for the period 1990–2008.

Activity data

Data on fuel consumed as reductants for the purpose of production of ferro-alloy metals have been collected under the under the NGER Scheme from 2009 onwards. For the years 1990–2008, this level of fuel consumption has been derived using historical production volumes.

4.5.3 Aluminium production (2.C.3)

Source category description

Aluminium is a key source in the Australian inventory. Emissions from the consumption of fuels in the production of carbon anodes on-site, or as carbon anodes, are estimated for this source. Additional perfluorocarbon emissions resulting from process upsets are also reported under this category.

Aluminium is produced by the electrolysis of alumina in a series of complex electrode reactions. The overall reaction results in aluminium being produced at the cathode and carbon dioxide at the anode:

The electrolysis process is conducted in carbon-lined steel pots containing high purity carbon anodes. The cell electrolyte consists of a molten bath of cryolite (Na_3AlF_6) to which varying proportions of aluminium fluoride, calcium fluoride or lithium fluoride may be added to lower the melting point, decrease the density of the electrolyte and improve energy efficiency.

Carbon dioxide is primarily formed by the chemical reaction of oxygen (produced in the electrolysis process) with the carbon anode. During the electrolysis of alumina to aluminium, some of the CO₂ formed at the anode may be reduced to CO by a secondary reaction involving particles of aluminium or sodium.

Grijotheim and Welch (1980) report that for a typical 150kAmp pre-baked cell, the anode gas consists of 70–85 per cent CO₂ with the balance (15–30 per cent) as CO. Measurements conducted by the ADC at several Australian smelters indicate that approximately 10 per cent of the anode gas (by weight) consists of CO. On contact with air, the majority of the CO in anode gas is burnt to CO₂ immediately above the electrolyte.

The perfluorinated carbon compounds (PFC), tetrafluoromethane (CF₄) and hexafluoroethane (C₂F₆) are powerful greenhouse gases which are generated during the so-called anode effect in the production of aluminium.

The anode effect is characterised by an increase in cell voltage as a result of the cryolite bath becoming deficient in alumina.

There are four companies operating aluminium smelters in Australia; Alcoa, Tomago Aluminium Rio Tinto and Hydro Kurri Kurri.

In Australia, bauxite is refined to alumina in Western Australia (WA), Queensland (Qld) and the Northern Territory (NT). The in-house production of lime at alumina refineries in Qld and NT represents an industrial process source of CO₂ emissions, which are accounted for under 2.A.2.

Methodology

CO₂ emitted during the consumption of carbon anodes is reported as if all the carbon is oxidised to CO₂. Emissions from the production of carbon anodes for use in aluminium production are estimated on the basis of the quantities of coal tar, petroleum coke and coke oven coke consumed in the production process and plant-specific EFs. CO₂ emissions are derived using the equation:

$$E_{al} = A_i \cdot EC_i \cdot EF_i$$

Where A_i is the quantity of fuel type i consumed in the production of anodes
 EC_i is the energy content of each fuel type i
 EF_i is the CO₂ EF for each fuel type i

Facility specific PFC EFs have been estimated in accordance with accepted international measurement protocols (International Aluminium Institute (2006), *The Aluminium Sector Greenhouse Gas Protocol, Addendum to the WRI/WBCSD GHG Protocol*, USEPA, International Aluminium Institute (2008), *Protocol for Measurement of Tetrafluoromethane (CF₄) and Hexafluoroethane (C₂F₆) Emissions from Primary Aluminium Production*).

Choice of emission factor

CO₂ EFs have been applied to the quantities of fuels used in the production of anodes. One NGER reporting facility has derived facility-specific CO₂ EFs for coal tar and petroleum coke. It was assumed that the fuel specifications measured at this facility were equally applicable to all facilities.

The facility-specific fuel consumption EFs for anode production are confidential, however, the implied total CO₂ EF per unit of aluminium produced is shown in Table 4.20 and confirms that these values are within the historical range of IEFs and not significantly different to the mean of the values reported between 1990 and 2010.

In the case of emissions of perfluorocarbons, facility-specific EFs at all facilities have been estimated and sourced from the NGER Scheme from 2009 onwards. National average factors for previous years have been supplied by the Australian Aluminium Council based on collected information on individual facility factors.

Activity data

Data on coke oven coke, petroleum coke and coal tar consumption for the purpose of production of aluminium have been collected under the NGER Scheme from 2009 onwards. For the years 1990–2008 coal tar and petroleum coke consumption are derived from the carbon in the reported emissions and the typical composition of carbon anodes used in the aluminium production process.

Data on aluminium for the purposes of estimating emissions of PFCs has been obtained under the NGER Scheme for 2009 onwards and ABARES *Commodity Statistics* (various years) for 1990–2008.

Complete coverage of all aluminium producers has been maintained through the data collection mechanisms utilised throughout the time-series as listed above.

Table 4.20 Emission factors: kg per tonne of aluminium production 1990, 2000–2020

Year	CO ₂ ^(a)	CF ₄	C ₂ F ₆

Source: NGER 2009–onwards, Beyond Neutral 2008, GHD 2009c. (a) IEF including production and consumption of anodes.

The carbon anode consumed in aluminium smelting is approximately 3 per cent sulphur by weight. Based on the assumption that 413 kg of carbon from the carbon anode is oxidised (consumed) for each tonne of aluminium produced, this implies that approximately 12.77 kg of sulphur and 25.54 kg of sulphur dioxide are oxidised per tonne of aluminium produced.

4.5.4 Magnesium production (2.C.4)

The inventory includes experimental quantities of SF₆ used between 1996 and 2000 as a cover gas in magnesium foundries preparatory to the development of a commercial magnesium casting plant (which was not, ultimately, commercially viable). The data on SF₆ use for this experimental foundry was supplied by CSIRO.

4.5.5 Lead production (2.C.5), zinc production (2.C.6), other (2.C.7)

Source category description

In Australia the Lead Production, Zinc Production and Other source categories includes emissions from the production of lead, zinc, copper, nickel, and silver. There are 10 major companies involved in the production of Lead, Zinc and other metals in Australia. In Australia, the major zinc refinery, in Hobart, uses an electrolytic process, which is non-emissive. The major lead refinery, at Port Pirie, which also refines a small amount of zinc, uses blast furnace technology.

CO₂ emissions from the use of fossil fuels as reductants, or in the production of carbon anodes on-site, or as carbon anodes in these refineries are reported under this category. An equivalent deduction has been made from fuel consumption in stationary energy to ensure there is no double-count of fuels in the inventory.

CO₂ emissions from the consumption of limestone in the production of other metals are reported under 2.A.3.

Australia's metal ores are predominantly sulphide ores leading to the generation of SO₂ as a by-product of metal production. SO₂ emissions from metal production are reported under this category.

Methodology

Emissions from the consumption of reductants in the production of lead, zinc and other metals have been estimated using a tier 2 method. Emissions are estimated using country-specific energy contents and CO₂ EFs for relevant fuels or, in certain cases, based on facility-specific EFs.

Ore composition and stoichiometric relationships have been used to derive sulphur dioxide emission estimates for copper, lead, nickel, zinc, and silver. The general approach is illustrated using the example of zinc. Zinc occurs either as sulphide ores (ZnS) or carbonate ores (ZnCO₃). Australia's zinc production is predominantly from sulphide ores. The objective of the refining process to obtain primary refined zinc is to break the compound ore down by separating the sulphur from the zinc. Based on atomic and molecular weights, 0.980 tonnes of SO₂ will be released per tonne of primary refined zinc. EFs for other metals, based on stoichiometry relationships, are given in the Table 4.22.

Table 4.22 Sulphur dioxide emission factors for refined metals

Metal	Tonnes SO ₂ per tonne of refined metal
Lead	0.3
Zinc	1.0
Nickel	1.1
Silver	0.3
Copper	2.0

Choice of emission factor

EFs have been selected in accordance with the decision tree in section 1.4.1.

Time series consistency has been maintained by the application of values for EFs for 2009 for the period 1990–2008.

Activity data

Data on fuel consumed as reductants for the purpose of production of other metals have been collected under the NGER Scheme from 2009 onwards.

For the years 1990–2008, this level of reductant consumption has been derived using metal production data from the Department of Industry, Science, Energy and Resources (DISER 2020). For silver and nickel production, activity data for the pre-NGER Scheme period has been derived using metal production statistics from the Bureau of Resource and Energy Economics (BREE 2014), which covers the period up until 2013.

4.5.6 Uncertainties and time series consistency

The tier 1 uncertainty analysis in Annex 2 provides estimates of uncertainty according to IPCC source category and gas.

Activity data obtained under the NGER Scheme was compared with activity data obtained from the former EITEIs Program for each facility and with data obtained from GHD and Energreen consulting to ensure the consistent classification of sources and consistency of data.

Where facilities were newly identified from NGER data as emitting facilities for a category, estimates of fuel consumption were interpolated through the time period from the most recent year for which data was available to the year of commencement of the facility based on metal production estimates.

Where facility-specific EFs were identified from NGER data for particular facilities, in category 2.C.4, the reported EFs for 2007, 2008 and 2009 were interpolated for each facility between 2006 and the most recent year for which data were available.

4.5.7 Source specific QA/QC

This source category is covered by the general QA/QC of the greenhouse gas inventory in Chapter 1. Additional source specific quality control checks were undertaken to assess international comparability.

The Metal Products sector was reviewed independently by an international expert (Tsaranu) in 2007. The review was undertaken applying the same principles governing regular UNFCCC inventory desktop reviews. Small refinements were made to the iron and steel non-CO₂ methodology and general refinements made to the metal products chapter in response to recommendations made in this review.

Iron and steel

The consumption of coke as a reductant which is used as the basis of emissions from iron and steel can be compared between the primary data source under the NGER Scheme and the *Australian Energy Statistics* (DISER 2021). A secondary source of trend comparison is the production of crude steel.

It is apparent from this comparison that NGER coke consumption tracks very closely with crude steel production levels while DoEE coke data appear not to reflect the increase in crude steel production observed in 2010–11.

As a result of this QC measure, and in consultation with Department of Industry and Science (DIS), it was determined that NGER data were best to use for this particular source.

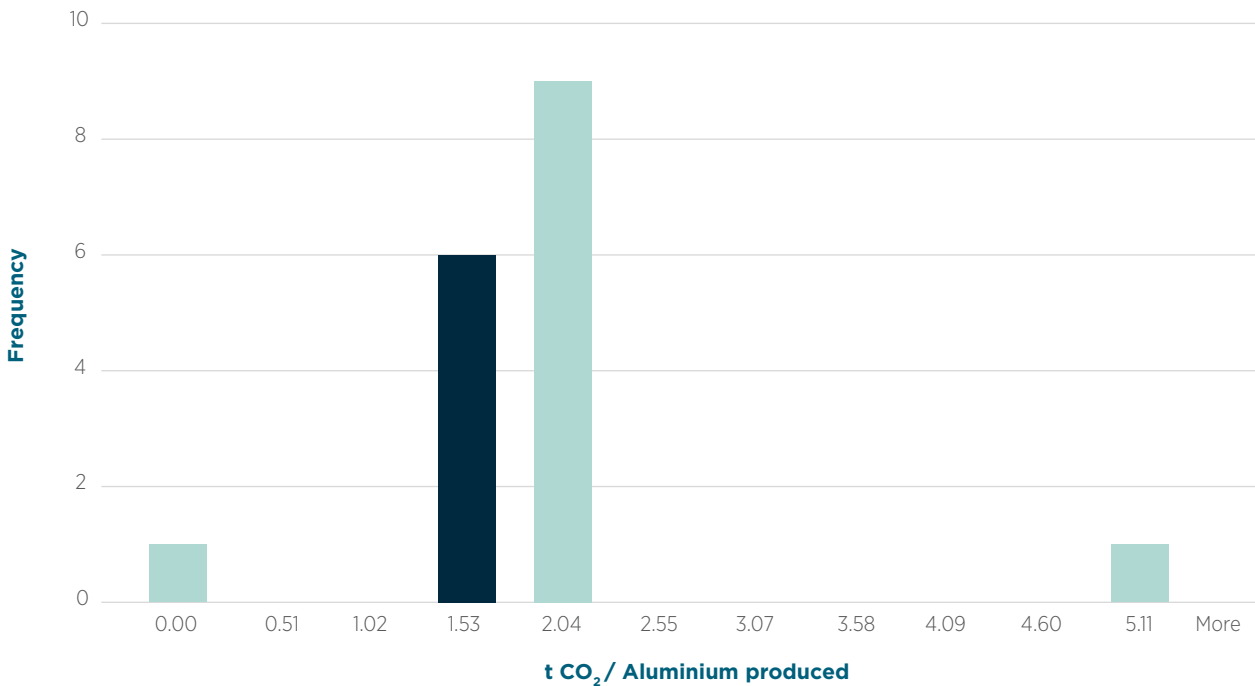

Aluminium

Emissions of PFCs by the Australian aluminium industry are a key category under both the level and trends analyses. Consequently, additional analysis has been performed to provide a comparison of Australian emission trends with those worldwide. The results of the comparison show that the trend in emissions per unit of production in Australia is very close to that observed worldwide. The decline in PFC emissions per unit of aluminium production in Australia since 1990 has mirrored the decline internationally (94 per cent), whereas the International Aluminium Institute (2020) reports a decline of 90 per cent between 1990 and 2019 worldwide. Emissions per unit of production reported by Australia are lower than the global averages, reflecting relatively modern plant and efficient operation, although this difference has narrowed slightly over time.

Monitoring of PFC concentrations occurs at the Cape Grim Baseline Air Pollution Station in Tasmania. Analysis of the observed atmospheric data has been undertaken by the CSIRO and compared to the emissions estimates in the inventory. Estimates of CF4 and C2F6 emissions based on the measured data are in reasonable agreement with inventory estimates for 2020 (CSIRO 2021).

The quantity of CO₂ per tonne of aluminium produced has been compared with that from other Annex I parties reporting emissions from this source. The results of this comparison are shown in Figure 4.7.

Figure 4.7 Aluminium production implied emission factors for Annex I countries (2019 Inventory) and Australia (2020 Inventory)

Note: In the figure above, Australia's IEF is located within the dark range.

The CO₂ IEF for aluminium production for Australia ranges between 1.40 t CO₂/t aluminium produced and 1.78 t CO₂/ t aluminium produced. IEFs fluctuate observed year on year according to the quantities of carbon-based fuels used to produce anodes.

Statistical analysis indicates that the IEF for aluminium production for Australia (in the shaded column above) is not significantly different to the factors reported by other Annex I parties.

In order to maintain continuity in the compilation of industrial processes emissions estimates, the Department engaged the external consultant previously used to collect activity data and EF information to undertake a quality control assessment of the full time series of activity data, EFs and emissions estimates. This work is of particular importance in *industrial processes and product use* where confidentiality of historical activity data pose some challenges for the assessment of time series consistency.

4.5.8 Recalculations since the 2019 Inventory

No recalculations were undertaken in the Metal Industry sector in this submission as set out in Table 4.23.

Table 4.23 2.C Metal Industry: recalculation of total CO₂-e emissions (Gg), 1990–2019

Year	2021 Submission	2022 Submission	Change	Change
	Gg CO ₂ -e	Gg CO ₂ -e	Gg CO ₂ -e	per cent

2018	10,976	10,976	-	0%
2019	10,940	10,940	-	0%

4.5.9 Planned improvements

All activity data, methodologies and emission factors are kept review.

4.6 Source Category 2.D Non-Energy Products from Fuels and Solvent Use

4.6.1 Source category description

Activities in the *Non-Energy Products from Fuels and Solvent Use* source category consist of CO₂ emissions arising from the oxidation of lubricants, as well as emissions of NMVOCs from solvent use, road paving and other activities.

Total net emissions estimated from *Non-Energy Products from Fuels and Solvent Use* were 178.4 Gg CO₂ and 124.8 Gg NMVOC in 2020 (Table 4.24). The main determinant of *Non-Energy Products from Fuels and Solvent Use* emissions from year to year is the quantity of the relevant product that is produced or used.

Table 4.24 Non-Energy Products from Fuels and Solvent Use NMVOC emissions 2020

Greenhouse Gas Source and Sink Categories	CO ₂ Emissions (Gg)	CH ₄ Emissions (Gg)	N ₂ O Emissions (Gg)	NMVOC emissions (Gg)
2D Non-Energy Products from Fuels and Solvent Use				
2.D.1 Lubricant Use	178.4			
2.D.2 Paraffin Wax Use	NE			
2.D.3 Solvent Use				111.4
2.D.4 Other				13.4

Emissions from Lubricant Use declined by 36.3 per cent or 0.1 Mt CO₂-e on 1990.

Emissions from *Solvent Use* decreased by 1.2 per cent or 1.0 Gg NMVOC between 1990 and 2020. Reductions in emissions from paint application have been offset by increases in emissions from degreasing and dry cleaning and other.

Surface coating operations involve the application of paint, varnish, lacquer or paint primer for decorative or protective purposes. Thinning solvents are normally used to dilute surface coating formulations or for cleaning purposes. Surface cleaning or degreasing operations involve the removal of materials such as oils, grease, waxes and moisture from surfaces. Chemical products manufacture and processing covers paint and ink manufacturing. General solvent use and consumer cleaning by the domestic and commercial sectors covers a large range of products including Domestic and Commercial Aerosol Products; Other Domestic and Commercial Products; and Consumer Cleaning Products.

Cutback bitumen is the most common form of primer used in Australia to protect roads from excessive wear. Cutback bitumen primers and primer binders are manufactured from refined bitumen which are 'cutback' (i.e. blended) with petroleum solvents. NMVOC emissions occur during the mixing of bitumen batches, stockpiling, application and curing of the road surface.

No consumption of Paraffin Wax is reported by DISER due to only trivial amounts being consumed in Australia – emissions are not estimated.

Methodology

Lubricant Use

Lubricants, together with bitumen and solvents, are non-fuel products of crude oil, which are included in the energy statistics compiled by DISER. It is assumed that 60 per cent of lubricants are not oxidised during engine operation, i.e. not actually combusted (Australian Institute of Petroleum, pers. comm. 1996). Therefore the stated DISER consumption of lubricants and greases is reduced by 60 per cent before emissions are estimated. Emissions of gases other than CO₂ are included with the emissions arising from fuel combustion in the engine type concerned in the relevant sector. Some lubricants may be incinerated subsequent to use. Any emissions from this source are included in the Waste sector. AD are currently not available to determine the quantity of lubricants consumed in 2-stroke engines. Accordingly, all emissions from lubricant use are accounted for in the *Industrial Processes* sector.

Road paving with asphalt

According to Treadrea (1995), for a system in equilibrium where the quantity of NMVOC used is constant each year and the average temperature conditions do not vary significantly from year to year, the quantity of flux and cutter lost to the atmosphere will be approximated by the quantity used each year.

It is assumed that the quantity of fluxed bitumen is negligible; the fraction of total bitumen consumption used in cutback bitumen is approximately 42 per cent (Australian Asphalt Pavement Association, pers. comm., 1995); and, the quantity of cutter added to the bitumen used in cutback bitumen is equal to 5.4 per cent (Treadrea 1995). Bitumen data are sourced from *Australian Energy Statistics* (DISER 2020).

NMVOC emissions from general solvent use and consumer cleaning

In accordance with IPCC 2006, per-capita EFs from the *EMEP/EEA air pollutant emission inventory guidebook 2016* have been adopted for estimating NMVOC emissions from Other Domestic/Commercial products and Consumer Cleaning Products. NMVOC emissions from general solvent use and consumer cleaning products are reported in Table 4.25. The mean population for the financial year is multiplied by the EF and the result is expressed in gigagrams (Gg). EFs are expressed in terms of per capita use per year.

EFs for general solvent use and consumer cleaning products are presented in Table 4.25.

Table 4.25 Emission factors for general solvent use and consumer cleaning products

Product	Emission Factor kg NMVOC/capita/yr
Domestic/Commercial Aerosol Products^(a)	
Household (cleaning) products	0.201
Care car products	0.161
Cosmetics and toiletries	0.355

4.6.2 Uncertainties and time series consistency

The tier 1 uncertainty analysis in Annex 2 provides estimates of uncertainty according to IPCC source category and gas. Time series consistency is ensured by use of consistent models, model parameters and datasets for the calculations of emissions estimates.

4.6.3 Source specific QA/QC

This source category is covered by the general QA/QC of the greenhouse gas inventory in Chapter 1.

4.6.4 Recalculations since the 2019 Inventory

No recalculations were undertaken in the Non-Energy Products from Fuels and Solvent Use sector in this submission as set out in Table 4.26.

Table 4.26 2.D Non-Energy Products from Fuels and Solvent Use: recalculation of total CO₂-e emissions (Gg), 1990–2019

2019	180	180	-	0 %

4.6.5 Planned improvements

All activity data, methodologies and EFs are kept under review. Particular focus will be on the investigation of AD to enable the re-allocation of emission from lubricant use in 2-stroke engines to the *Energy* sector.

4.7 Source Category 2.E Electronics Industry

4.7.1 Source category description

Whilst there is some small scale manufacture of electronics in Australia, in accordance with UNFCCC inventory reporting guidelines emissions associated with the use of fluorinated compounds in the electronics industry are considered negligible and are not estimated.

Australia has identified a small amount of specialty electronic components manufacturing, consuming around 20kg of NF_3 which is destroyed in the process.

It is also understood that negligible amounts of electronics cooling fluids containing NF_3 are consumed in Australia, confined to consumer use in personal computers and hobby applications.

4.8 Source Category 2.F Product Uses as Substitutes for Ozone Depleting Substances

4.8.1 Source category description

This sub-sector comprises emissions of synthetic gases from the use of hydrofluorocarbons (HFCs) in refrigeration and air conditioning, foam blowing, fire extinguishers, aerosols/metered dose inhalers and solvents.

The methodology used for compiling emissions estimates for this source category relates emissions to the stock and vintage of hydrofluorocarbon (HFC) gases in various equipment end-use categories and is described below under the heading "Methodology". Where equipment stock data are available (in the case of domestic refrigeration and air conditioning, motor vehicle air conditioning and metered dose inhalers), information on the vintage and lifetimes of the capital stock of appliances have been used to estimate emissions on a bottom up basis. Where these stock data are not available, a top-down approach has been used.

The method relies primarily on inputs of data on HFC imports (an estimate of potential emissions – there is no local production of HFCs in Australia) reported to the Department of Agriculture, Water and the Environment, under the *Ozone Protection and Synthetic Greenhouse Gas Management Act, 2003*. As part of the licensing conditions specified in the Act, quantities of gas imported in bulk and in pre-charged equipment are reported to the Department of Agriculture, Water and the Environment and these data are used for emissions estimation.

4.8.2 Methodology

Consistent with IPCC good practice, the methodology uses specified equations to estimate HFC emissions for each equipment type for three separate processes: a) initial losses that occur at the initial charging of the equipment; b) emissions from leakages during the life of the equipment and c) the emissions from the disposal of the equipment. Initial losses occur when an amount of bulk imported gas (Mb_{ijkt}) is allocated to a specific equipment type j. Emissions during the life of the equipment depend, in the first year, on the amount of imported bulk gas allocated to the equipment type j and the amount of gas in imports of precharged equipment of type j (Mpc_{ijkt}) and, for every year thereafter, on the opening stock of gas in the equipment type (S_{ijkt-1}) plus any replenishments of gas (R) in the equipment type that may have occurred in that year. Emissions at disposal depend upon the closing stock of gas of vintage k in year t (S_{ijkt}), the proportion of the equipment stock retiring in each year (α_{jkt}) and the quantity of gas recovered for destruction (D_{ijkt}).

The methodology is summarised by the following equations:

$$E_{ijkt} = Mb_{ijkt} * IL_{jt} + (S_{ijkt-1} + Mb_{ijkt} + Mpc_{ijkt} + R_{ijkt}) * (EF_{ij}) + (\alpha_{jkt} * S_{ijkt} - D_{ijkt})$$

$$S_{ijkt} = S_{ijkt-1} + Mb_{ijkt} + Mpc_{ijkt} + R_{ijkt} - E_{ijkt} - D_{ijkt}$$

$$R_{ijkt} = \sum_{t-1}^{t-z} E_{ijkt}$$

$$D_{ijktbase} = \alpha_{jkt} * S_{ijkt} * DF_{ijk}$$

$$D_{ijkt} = D_{ijktbase} / \sum_j \sum_k D_{ijktbase} * DTOT_t$$

and

$$E_t = \sum_i \sum_j \sum_k E_{ijkt}$$

Where E_t is the sum of emissions of all gases of type i from all equipment types j and vintages k in year t

E_{ijkt} is the emissions of gas i from equipment type j and vintage k in year t

S_{ijkt-1} is the opening stock of gas i from equipment type j and vintage k in year t

S_{ijkt} is the closing stock of gas i from equipment type j and vintage k in year t

Mb_{ijkt} is the quantity of bulk import of gas i allocated to equipment type j for vintage k if k = year t

Mpc_{ijkt} is the quantity of gas i in imports of pre-charged equipment type j for vintage k if k = year t

R_{ijkt} is the amount of replenishment of the stock of gas i for equipment type j and vintage k in year t

EF_{ijkt} is leakage rate of gas i from equipment type j and vintage k in year t (in the first year of operation, EF is divided by 2 - assuming equipment is in operation for an average of 6 months)

IL_{jt} is the initial loss rate from equipment type j in year t

α_{jkt} is the proportion of the capital stock of equipment type j and vintage k retired in year t

$\sum_{t-z}^{t-1} E_{ijkt}$ is the sum of initial and annual emissions from t-z to t where t is the current year and z is the number of years between replenishments

D_{ijkt} is the amount of gas i destroyed from equipment type j and vintage k in year t

DF_{ijkt} is the base destruction factor for gas i destroyed from equipment type j and vintage k in year t

$D_{ijktbase}$ is estimated base amount of gas i destroyed from equipment type j and vintage k in year t

$DTOT_t$ is the actual total gas destroyed reported by Refrigerant Reclaim Australia

The initial loss rate (IL_{jt}) and annual loss rates (EF_{jkt}) applied to each vintage of each equipment type are a mix of IPCC 2006 defaults (the mid-point of specified ranges) and country specific factors.

Replenishment and disposal

Commercial equipment is assumed to be replenished to full charge every two years.

Light vehicle air conditioners are assumed to be replenished to full charge once after 6 years of operation.

Sensitivity testing of the impact of these assumptions on emissions is provided in the QA/QC section. Lifetime emissions are not affected by these assumptions, while the time profile of emissions is considered to be not significantly sensitive to these assumptions.

Average equipment lifetimes are based on country-specific expert assessment for refrigeration and air-conditioning equipment, and on IPCC default values for other equipment classes. A constant proportion of the equipment stock (α_{jkt}) is assumed to be disposed over a period of time centred on the midpoint of the average equipment lifetime.

The charge remaining in equipment at retirement is assumed to be emitted to the atmosphere, subject to reclaim and destruction reported by Refrigerant Reclaim Australia (RRA), the operator of the sole product stewardship scheme for refrigerants in Australia. The total amount of HFC gas recovered for destruction by RRA data is allocated between different equipment classes in assumed proportions informed by IPCC default recovery factors. Approximately 20% of retiring gas was captured and destroyed in 2020.

Table 4.27 Hydrofluorocarbons: key assumptions concerning average equipment life, initial and annual losses and replenishment rates, by equipment type

End Use Category	Average equipment life ^(a,b,d)	Loss on initial charge ^(a)	Annual loss ^(a,d)	Replenishment ^(c)	Emissions Estimation Method
	Years	per cent	per cent		
Commercial refrigeration					
Stand-alone commercial applications	12	1.75	7.2	Full replenishment every 2 years	Method 3
Medium and large commercial applications	15	1.75	11.8 – 13.0	Full replenishment every 2 years	Method 3
Industrial commercial applications	23	1.75	15.7 – 17.5	Full replenishment every 2 years	Method 3
Domestic refrigeration	14.5	0.6	1.7	No replenishment	Method 2
Transport refrigeration	7	5.1	15.7 – 20.0	Full replenishment every 2 years	Method 3
Light vehicle air conditioning	11.5	0.4	6.7 – 10.0	Full replenishment at 6 years	Method 1
Heavy vehicle air conditioning	13	0.4	10.8	Full replenishment every 2 years	Method 3
Domestic stationary air conditioning					
Refrigerated portable air conditioners	11.5	0.6	2.5	No replenishment	Method 2
Split system air conditioners	13.5	0.6	3.5 – 4.0	No replenishment	Method 2
Packaged air conditioners	13.5	0.6	2.5 – 4.0	No replenishment	Method 2
Commercial air conditioners	22	5.1	4.5 – 6.0	Full replenishment every 2 years	Method 3
Foams (open and closed cell)	20.5	60.0	2.3	No replenishment	Method 4
Aerosols	2.5	0.0	50.0	No replenishment	Method 4
Fire	10.5	0.4	5.0	Full replenishment every 2 years	Method 4
Metered Dose Inhalers	2	0.0	50.0	No replenishment	Method 3

Bulk gas activity data allocation methods

Bulk imported HFC gas allocations to equipment types are undertaken in 3 ways depending on what information is available about equipment stocks and production levels. These are identified below as methods 1 to 3.

Bulk gas demand is first estimated for classes of equipment where data on equipment stocks is available, then the residual bulk gas is allocated to the remainder of equipment types.

Method 1 covers the allocation of bulk gas to light vehicle air conditioning. Vehicle stocks by vintage in each inventory year are available from data underpinning the estimation of emissions from road transport. The following equation is used:

$$G_{demmv} = G_{dpmv} + G_{drmv}$$

$$G_{dpmv} = (New_{mv} - Imp_{mv}) \times Chg_{mv}$$

Where G_{demmv} is total gas demand for production and replenishment for motor vehicle air conditioners
 G_{dpmv} is gas demand for domestic production for motor vehicle air conditioners
 G_{drmv} is the gas demand for replenishment for motor vehicle air conditioners – assumed to be total replacement of lost gas in the 5th year of operation
 New_{mv} is new additions to the motor vehicle stock – based on motor vehicle census data used for the estimation of emissions for the transport sector
 Imp_{mv} is imports of pre-charged motor vehicle air conditioners
 Chg_{mv} is the unit charge of motor vehicle air conditioners

Method 2 covers the allocation of bulk gas to domestic refrigeration and air conditioning. Total stocks of domestic refrigerators and air conditioners are estimated based on data available from the Australian Bureau of Statistics. To achieve mass balance, the method includes a ‘stock in storage’ factor, where a proportion of imported units are held over for installation in a following year. The following equation is used:

$$G_{demdrac} = G_{dpdrac} + G_{drdrac}$$

$$G_{dpdrac} = (Exp_{drac} - Imp_{domrac} + Ret_{drac} + \Delta S_{drac}) \times Shr_{hfc} \times Chg_{drac}$$

Where $G_{demdrac}$ is total gas demand for production and replenishment for domestic refrigerators and air conditioners
 G_{dpdrac} is gas demand for domestic production for domestic refrigerators and air conditioners
 G_{drdrac} is the gas demand for replenishment for domestic refrigerators and air conditioners – no replenishment assumed
 Exp_{drac} is the exports of domestic refrigerators and air conditioners
 Ret_{drac} is the retirements of domestic refrigerators and air conditioners – based on assumptions about the operational life of each equipment type
 ΔS_{drac} is the change in stock of domestic refrigerators and air conditioners calculated according to:
 $CS_{drac} - OS_{drac}$

Where CS_{drac} is the closing stock of domestic refrigerators and air conditioners
 OS_{drac} is the opening stock of domestic refrigerators and air conditioners
 Imp_{drac} is the imports of domestic refrigerators and air conditioners adjusted for stock in storage
 $= Imp_{pcedrac} \times P_{inst}$

Where $Imp_{pcedrac}$ is total imports of pre-charged domestic refrigerators and air conditioners
 P_{inst} is the proportion of pre-charged domestic refrigerators and air conditioners installed in the year of import
 Shr_{hfc} is the share of domestic production using HFCs
 CHG_{drac} is the unit charge of domestic refrigerators and air conditioners

Bulk gas demand is summed for method 1 and 2 equipment types as follows:

$$G_{\text{demtotal}} = G_{\text{demmv}} + G_{\text{demdrac}}$$

Where G_{demtotal} is total demand for gas for production and replenishment for motor vehicle air conditioners and domestic refrigeration and air conditioners
 G_{demmv} is total gas demand for production and replenishment for motor vehicle air conditioners
 G_{demdrac} is total gas demand for production and replenishment for domestic refrigerators and air conditioners

After bulk gas demand for method 1 and 2 equipment types is allocated, the residual gas is allocated to method 3 and 4 equipment types.

Method 3 covers commercial refrigeration and air conditioning, and metered dose inhalers. Method 4, is a simplified version of Method 3 which does not account for equipment level data and covers foams, aerosols and fire protection equipment. There is no equipment stock information available for these equipment types. Gas is allocated to these equipment types according to the following equation:

$$G_{\text{res}} = G_{\text{bulk}} - G_{\text{demtotal}}$$

$$G_{\text{resi}} = G_{\text{res}} \times \text{Shr}_{\text{resi}}$$

Where G_{res} is the residual gas available to commercial refrigeration and air-conditioning, metered dose inhalers, foams, aerosols and fire protection equipment
 G_{bulk} is total bulk gas imported available to all equipment
 G_{demmv} is total gas demand for production and replenishment for motor vehicle air conditioners
 G_{demdrac} is total gas demand for production and replenishment for domestic refrigerators and air conditioners
 G_{resi} is the residual gas available to equipment type i
 Shr_{resi} is the share of residual gas used in equipment type i – this value is based upon end use data provided annually by DAWE

The amount of bulk gas estimated to be used in filling of newly manufactured products in method 3 and 4 may vary substantially between years, as it depends on the quantity of bulk imports remaining after demand for filling method 1 and 2 products and replenishments across all product categories is satisfied

Activity data: HFC gas imported into Australia

Data on imports of HFC gases are reported to DAWE under licensing arrangements operating under the *Ozone Protection and Synthetic Greenhouse Gas Management Act, 2003*.

Imports of bulk gas are allocated initially to individual end uses on the basis of a consideration of the amount of gas required for domestic production and replenishment/servicing and retrofitting for the sources which are estimated on a bottom-up basis (gas demand in domestic refrigeration, packaged, split and refrigerated portable air-conditioning and light vehicle air conditioning). After this initial gas demand is satisfied, the residual bulk gas is allocated to the remaining end use categories in proportion to the information on use as reported by licensees under the Act. The sensitivity of these allocations on emissions estimates has been tested and the results are reported in the QA/QC section. The results show that lifetime emissions are not affected by these assumptions; the time profile of emissions – whilst impacted – is not considered sensitive to these assumptions.

Quantities of gas imported in bulk and contained in pre-charged equipment by end-use category are shown below.

Table 4.28 End-use allocation of imports of bulk and pre-charged HFC gas, 2020 (Mt CO₂-e)

End Use Breakdown	Bulk Imports	Pre-charged imports	Total
	(Mt CO ₂ -e)	(Mt CO ₂ -e)	(Mt CO ₂ -e)
Refrigeration	8.16	0.37	8.53
Transport refrigeration	0.53	0.18	0.71

Backcasting

Collection of data on HFC imports under the *Act* commenced in the 2005 financial year. There are no data available on the import of HFCs for years prior to 2005. It is therefore necessary to backcast import data to enable an estimate of the bank of gas and associated emissions. For each of the end-use categories information on the transition from the use of CFC refrigerants to HFC refrigerants provided in Burnbank 2002 was used to determine a time series of HFC imports up to 2005 when actual import data are available.

Overview of the stocks of gas in operating equipment

Figure 4.9 shows the growth in the stock of synthetic gas in operating equipment.

The chart shows significant growth in gas contained in commercial refrigeration systems, motor vehicle air conditioners and split system air conditioners. The general growth in the stock of gas over the time series reflects the transition from CFC to HFC refrigerant use associated with the Montreal Protocol controls on CFC use. In addition to the transitional trend, the recent strong growth in commercial refrigeration systems reflects similar growth in Australia's economy, whilst the growth in motor vehicle air conditioning and residential split systems reflects declines in relative prices of imported residential air conditioning systems as well as a transition in the vehicle fleet to more modern air conditioned vehicles.

The total stock and emissions from the consumption of halocarbons is shown in Table 4.29.

Figure 4.8 Growth in the bank of HF gas in operating equipment (Mt CO₂-e)

Table 4.29 Halocarbons: estimated stock and emissions: all equipment types

Refrigeration and air conditioning (2.F.1)

The refrigeration and air-conditioning sector accounts for the majority of HFC consumption in Australia. Emissions from any piece of equipment include both the amount of chemical leaked during initial charging of equipment and the amount emitted during service life. Emissions also occur at equipment disposal. The disposal emission equation assumes that a certain percentage of the chemical charge will be emitted to the atmosphere when that vintage is discarded. Disposal emissions are thus a function of the quantity of chemical contained in the retiring equipment and the proportion of chemical released at disposal. The rate at which equipment is retired is based on IPCC default average service-lives for the various types of equipment.

Domestic Refrigeration and freezers

A bottom-up capital stock model was used to determine a time series for the stock of gas contained in domestic refrigeration and freezers. The estimates are based on data on the number of households and the numbers of domestic fridge freezers found in each household in Australia (ABS 2008a and ABS 2008b) and pre-charged equipment import data collected under the *Ozone Protection and Synthetic Greenhouse Gas Management Act*. Stock estimates in recent years are based on Expert Group projections and reflect a transition to the use of hydrocarbon refrigerants in place of HFCs.

Average charges per unit for domestic refrigerators are based on the pre-charged equipment data collected under the *Act*. Service life emissions are derived using Expert Group 2018.

Domestic production of household refrigerators no longer takes place in Australia with the last producer Fisher and Paykel completing the relocation of their remaining production facility to Thailand in August 2009¹⁰.

The number of newly manufactured products filled with HFC gas is inferred as the balance of opening and closing stock numbers, imports/exports and retirements. The estimated amount of gas filled may vary substantially between years; where the above balance is negative, this amount is assumed to be zero.

It is assumed that no replenishment of gas losses from domestic refrigerators takes place as the units contain small well-sealed charges of gas.

Unit disposals are based on an average lifetime of 15 years with the first units in each vintage retiring after 5 years.

Table 4.30 shows the capital stocks, HFC stock and emissions from domestic refrigeration.

Domestic air conditioning

Stationary air conditioning comprises refrigerated portable, split and packaged systems. Emissions from this sub category are estimated on a bottom-up basis using equipment population estimates based on numbers of households and white-goods data provided in ABS 2008c, and pre-charged equipment import data. Table 4.31, Table 4.32 and Table 4.33 show the capital stocks, HFC stocks and emissions from the three types of air conditioning equipment.

Leakage rates are based on country-specific expert assessment.

Quantities of residual gas disposed in each vintage are based on the IPCC average equipment life of 15 years. The first disposals of gas are assumed to occur after 6 years of operation.

Mobile air-conditioning (Passenger Cars)

Emissions from the use of air conditioners in passenger cars and light commercial vehicles (vehicles under 3.5 tonnes gross vehicle mass) are also estimated on a bottom-up basis. Data on the stock of motor vehicles obtained from the ABS *Motor Vehicle Census* (ABS 2020) have been used to construct a capital stock model. The stock of light vehicles, the stock of HFC gas contained in motor vehicle air-conditioners and the associated emissions are reported below. It is assumed that all new units manufactured from 1995 onwards contain HFC-134a.

Table 4.34 Halocarbons: estimated stock and emissions: light vehicle air conditioners

Source: (a) ABS 2019a; Includes stocks not containing HFC refrigerants.

The stock of gas has been compiled using the ABS data on light vehicle stocks, import data on number of units imported and average charge, and assumptions about proportions of each vintage with air-conditioning for early years in the time series. Assumptions needed on the percentage of pre-1995 vehicles retrofitted with HFC-134a units to estimate an addition to the stock of gas were taken from Burnbank 2002.

The number of newly manufactured vehicles filled with HFC gas is estimated as the balance of increases in vehicle stocks, less the number of vehicles imported in that year. When the number of imported vehicles exceeds the increase in new vehicle stocks, it is assumed that no domestic filling of gas into newly manufactured vehicles occurs.

Analysis has shown that the charge in pre-filled units does not significantly differ between model years in the fleet, indicating that despite a general trend of increasing vehicle sizes, there is not an increase in air-conditioning equipment charge due to being offset by more efficient equipment.

Equipment disposals are based on the IPCC default average life-span of 12 years with the first units of each vintage retiring after 5 years of operation.

Mobile air conditioning (heavy vehicles)

This source category comprises emissions from air conditioning units in vehicles over 3.5 tonnes gross vehicle mass.

The quantities of imported gas are allocated to heavy vehicle air conditioning on the basis of pre-charged equipment as reported under the *Ozone Protection and Synthetic Greenhouse Gas Management Act* and a proportion of bulk gas adjusted for gas demand in domestic refrigeration and air conditioning and mobile air conditioning. Once the gas required for loss replenishment needs is satisfied, the remaining bulk gas is allocated to charging new locally produced units.

Country specific leakage rates are applied to each gas vintage. Quantities of residual gas disposed in each vintage are based on the IPCC average equipment life of 12.5 years and the assumption that gas losses are replenished after every 2 years of a unit's life. The first disposals of gas occur after 5 years of operation.

Transport refrigeration

Transport refrigeration comprises vehicle and self-powered refrigeration units used in commercial vehicles.

Quantities of imported gas are allocated to transport refrigeration on the basis of pre-charged equipment as reported under the *Ozone Protection and Synthetic Greenhouse Gas Management Act* and a proportion of bulk gas adjusted for gas demand in domestic refrigeration and air conditioning and mobile air conditioning. Once the gas demand for loss replenishment is satisfied, the remaining bulk gas is allocated to charging new locally produced units.

Country-specific leakage rates are applied to each gas vintage. Quantities of residual gas disposed in each vintage are based on the IPCC average equipment life of 7 years and the assumption that gas losses are replenished after every 2 years of a unit's life up to the year of disposal. It is assumed that the first disposals of gas occur after 5 years of operation.

Commercial refrigeration

Commercial refrigeration comprises stand-alone, medium and large and industrial refrigeration units and is the most significant user of synthetic gases in Australia.

The quantities of imported gas are allocated to commercial refrigeration on the basis of pre-charged equipment imports and a proportion of bulk gas adjusted for gas demand in domestic refrigeration and air conditioning and mobile air conditioning. Once the gas required for loss replenishment needs is satisfied, the remaining bulk gas is allocated to charging new locally produced units.

Country-specific leakage rates are applied to each gas vintage. Quantities of residual gas disposed in each vintage are based on the IPCC average equipment life values and the Department's assumption that gas losses are replenished after every 2 years of a unit's life. It is assumed that the first disposals of gas occur after 5 years of operation.

Commercial air conditioning

Commercial air conditioning covers the use of chiller units used in commercial buildings.

Quantities of imported gas are allocated to commercial refrigeration on the basis of pre-charged equipment imports and a proportion of bulk gas adjusted for gas demand in domestic refrigeration and air conditioning and mobile air conditioning. Once the gas demand for loss replenishment is satisfied, the remaining bulk gas is allocated to charging new locally produced units.

Country-specific leakage rates are applied to each gas vintage. Quantities of residual gas disposed in each vintage are based on an average equipment life of 22.5 years and the assumption that gas losses are replenished after every 2 years of a unit's life up to the year of disposal. The first disposals of gas occur after 5 years of operation.

Foam Blowing Agents (2.F.2)

The quantities of imported gas are allocated to foam on the basis of a proportion of bulk gas adjusted for gas demand in domestic refrigeration and air conditioning and mobile air conditioning.

IPCC default leakage rates are applied to each gas vintage. Quantities of residual gas disposed in each vintage are based on the IPCC average equipment life of 20.5 years. The first disposals of gas occur after 5 years of operation. There is no recovery or replenishment assumed in foams.

Foams are given emission profiles depending on the foam type (open cell or closed cell). Open cell foams are assumed to be 100 per cent emissive in the year of manufacture. Closed cell foams are assumed to emit a portion of their total HFC content upon manufacture, a portion at a constant rate over the lifetime of the foam, and a portion at disposal. Emissions from both open and closed cell foams are estimated as one source using the vintage stock model with an average initial charge and annual operation leakage rate.

Table 4.39 Halocarbons: estimated stock and emissions: foam

Fire Protection (2.F.3)

The quantities of imported gas are allocated to fire extinguishers on the basis of pre-charged equipment imports and a proportion of bulk gas adjusted for gas demand in domestic refrigeration and air conditioning and mobile air conditioning. Once the gas required for loss replenishment needs is satisfied, the remaining bulk gas is allocated to charging new locally produced units.

IPCC default leakage rates are applied to each gas vintage. Quantities of residual gas disposed in each vintage are based on the IPCC average equipment life of 10 years and the assumption that gas losses are replenished after every 2 years of a unit's life. The first disposals of gas occur after 5 years of operation.

The UNFCCC expert review of Australia's 2008 submission recommended that the completeness of the *industrial processes and product use* estimates be improved by inclusion of estimates of emissions from PFC use in fire extinguishers. In response, the Australian Fire Protection Association (FPA) was consulted and they confirmed that the ozone depleting or synthetic greenhouse fire fighting gases most common in Australia are: FE 227 (HFC 227ea), FM 200 (HFC 227ea), NAF-S-III (HCFC Blend A) and NAF-P-III (HCFC Blend C). The use of other gases is considered quite rare. On this basis, PFC use in fire extinguishers is considered to be 'Not Occurring'.

Aerosols/Metered Dose Inhalers and Solvents (2.F.4 and 2.F.5)

Emissions from these sectors come from two sources: product use and fugitive emissions associated with product manufacture. Emissions from solvent and aerosol product use can be assumed to be 100 per cent of the charge size (100 per cent of consumption over the life of the product).

The quantities of bulk gas imported into Australia and allocated for use in aerosols and solvents is based on the proportion of reported end use adjusted for gas requirements in domestic refrigerator and air conditioning and mobile air conditioning. No replenishment is assumed to occur. Therefore all gas imported in bulk goes into charging domestically produced stock.

The complete charge of gas from an aerosol application is assumed to be lost at a base rate of 50 per cent per year.

There is no domestic production of metered dose inhalers (MDIs) in Australia. Imports of metered dose inhalers containing HFCs are not covered by the *Ozone Protection and Synthetic Greenhouse Gas Management Act (2003)*. Consequently, emissions of HFCs from the use of metered dose inhalers are estimated on a bottom up basis. Estimates of the imports of gas contained in metered dose inhalers is based on information supplied by the Department of Sustainability, Environment, Water, Population and Communities (SEWPaC) on the number of MDIs imported into Australia in 2009 and a per-capita based estimation of imports up to that year. Assumptions about the penetration of HFC propellants in imported MDIs are based on information in Burnbank 2002. On average, each imported unit is pre-charged with 14 grams of HFC-134a based on information supplied from SEWPaC.

Emissions from MDIs are estimated according to the same assumptions used for aerosols and solvents.

The growth in imports and the bank of HFC in metered dose inhalers along with the associated emissions from this bank is shown below.

4.8.3 Source specific QA/QC

Data are obtained by DAWE from companies under licensing arrangements established under the *Ozone Protection and Synthetic Greenhouse Gas Management Act (2003)* and has been subject to verification against known published sources (the Australian Bureau of Statistics data on imports of HFC-134a).

The Consumption of Halocarbons and SF₆ sector were reviewed independently by an international expert (Tsaranu 2007). The review was undertaken applying the same principles governing regular UNFCCC inventory desktop reviews. The emissions model was reviewed previously by Burnbank consulting. The outputs of the domestic refrigeration and mobile air-conditioning components of the model were cross-checked against those reported in Burnbank 2002 with close agreement between the two sets of estimates.

Mass balances

An additional comprehensive review of this source was undertaken in which HFC balances were completed to ensure that:

- all imported gas in bulk and pre-charged equipment is assigned to an appropriate end-use category, and
- stock changes and emissions and gas destruction were fully tracked and accounted for.

The results of these allocation and stock balances are presented in Tables 4.43 and 4.44.

Checks are undertaken to ensure that the sum of bulk gas demand for domestic production and replenishment of leaked gas equals total bulk imports. Table 4.45 shows this gas balance check.

Table 4.43 Halocarbons: balance sheet – allocations of imported gas (Mt CO₂-e)

External verification through atmospheric testing

Monitoring of atmospheric HFC concentrations has been undertaken by the Commonwealth Scientific and Industrial Research Organisation (CSIRO) at the Cape Grim Baseline Air Pollution Station in Tasmania since the mid 1990's. The verification process undertaken independently by CSIRO lags the official inventory submission by one year. CSIRO uses inverse modelling techniques to derive an estimate of national HFC emissions based on atmospheric measurements of HFC concentrations.

Estimated HFC emissions are compared to those estimated by CSIRO through measurements conducted at the Cape Grim monitoring station in Tasmania (CSIRO 2021). The comparison of estimates based on Cape Grim measurements with inventory estimates are shown below. The average variance between the two estimates is 34%.

Figure 4.9 Comparison of Inventory HFC emission estimates with estimates derived from Cape Grim measurement data

The 2006 IPCC Guidelines identify fluorinated gases as being among the most suitable for which inverse modelling could provide verification of emissions estimates (p 6.21). As inverse modelling can be prone to natural source interference, F-gases are well suited to this approach as they have no natural sources. The remote location of the Cape Grim monitoring station also reduces the likelihood of measurement error from international sources. Additionally, there are no sinks for F-gases and therefore changes in concentrations reflect changes in emissions.

Gas species fluctuations observed at Cape Grim are also used to calibrate gas speciation in the HFC emissions model. Comparisons of CSIRO and NIR estimates of individual HFC gas species are shown below.

Figure 4.10 Comparison of HFC emissions by species (t)

Sensitivity testing

In addition to the HFC balances documented above, sensitivity analysis was undertaken to assess the impacts of changes to the allocation of bulk gas to end use as well as changes to the assumptions about replenishment rates in equipment. These two elements of the HFC model are where important assumptions are made about the areas of consumption of imported gas and the servicing/replenishment habits of the consumers of this gas.

The effect of end use allocation on total emissions was tested by altering the percentage of bulk gas allocated to domestic, commercial and transport refrigeration (which is the biggest user of imported bulk gas) by 1 per cent, 5 per cent, 10 per cent and 20 per cent in all years with the residual gas allocated equally among the other end-use categories. In addition to this change in allocation, all gas imports are ceased after 2009.

Table 4.45 Halocarbons: results of sensitivity testing of allocation assumptions (Mt CO₂-e)

End use allocation	Allocation assumptions (per cent of total bulk imports)				
	Base	Case 1	Case 2	Case 3	Case 4
Aerosols/solvents	2 %	2 %	3 %	4 %	5 %
Domestic/Commercial/ Transport refrigeration	60 %	59 %	55 %	50 %	40 %
Fire	2 %	2 %	3 %	4 %	5 %
Foam	2 %	2 %	3 %	4 %	6 %
Mobile air conditioning	25 %	25 %	26 %	27 %	28 %
Mobile OEM	1 %	1 %	2 %	3 %	5 %
Stationary air conditioning	8 %	8 %	8 %	9 %	11 %
Emissions in 2008 (Mt CO₂-e)					
Commercial refrigeration	3.23	3.19	3.06	2.89	2.50
Domestic refrigeration	0.04	0.04	0.04	0.04	0.04
Transport refrigeration	0.31	0.31	0.30	0.28	0.24

Aerosols	0.13	0.15	0.20	0.27	0.43
Foams	0.13	0.14	0.18	0.24	0.37
Fire	0.05	0.06	0.08	0.11	0.18
Metered dose inhalers	0.14	0.14	0.14	0.14	0.14
Total	5.75	5.75	5.74	5.73	5.70
per cent change in total emissions compared with emissions in the base case		-0.04 %	-0.19 %	-0.40 %	-0.86 %

The results show that even with a 33 per cent change in bulk gas allocation from domestic, transport and commercial refrigeration to other end use categories, total emissions in 2008 are changed by only 0.9 per cent. This suggests that the estimate of emissions in any given year is relatively insensitive to changes in the allocation of bulk gas.

Figure 4.11 shows gas imports under the base end use assumption and each of the re-allocation assumptions. It can be seen that the gas diverted from domestic, commercial and transport refrigeration is re-allocated primarily to aerosols, foams, and fire protection. In total however, gas imports are unchanged as a result of the re-allocation.

Under scenario 5 (a 33 per cent re-allocation from domestic, commercial and transport refrigeration), approximately 1 million tonnes is re-directed in equal proportions towards aerosols, foam and fire protection. This results in a reduction in emissions of 0.79 million tonnes CO₂-e in domestic, commercial and transport refrigeration and a corresponding increase of 0.66 million tonnes in aerosols, foams and fire protection. The residual gas is accounted for as gas recovered and destroyed and stock change in the bank of gas in operating equipment.

Figure 4.11 Halocarbons: sensitivity testing of allocation assumptions: 2008 (Mt CO₂-e)

Total cumulative differences in emissions and destruction under each allocation scenario between 1990 and 2050 (where the last of the current stock of operating equipment is retired) are shown in Figure 4.12. The chart shows that while differences occur in emissions in individual years the total gas either emitted or destroyed is unchanged over the life of each equipment type. The gas end-use re-allocation results in an increase in emissions for years where imports are occurring (up to 2009 in the case of this test), followed by a decrease in emissions relative to the base assumption from 2009 onwards.

Figure 4.12 Halocarbons: results of sensitivity testing of allocation assumptions: 1990–2050 (Mt CO₂-e)

As information about servicing and replenishment practices is limited, the replenishment assumptions have been devised by the Department.

The effect of assumptions about gas replenishment was tested by reducing the replenishment rates for all sources where replenishment occurs by 10 per cent, 20 per cent, 30 per cent and 50 per cent.

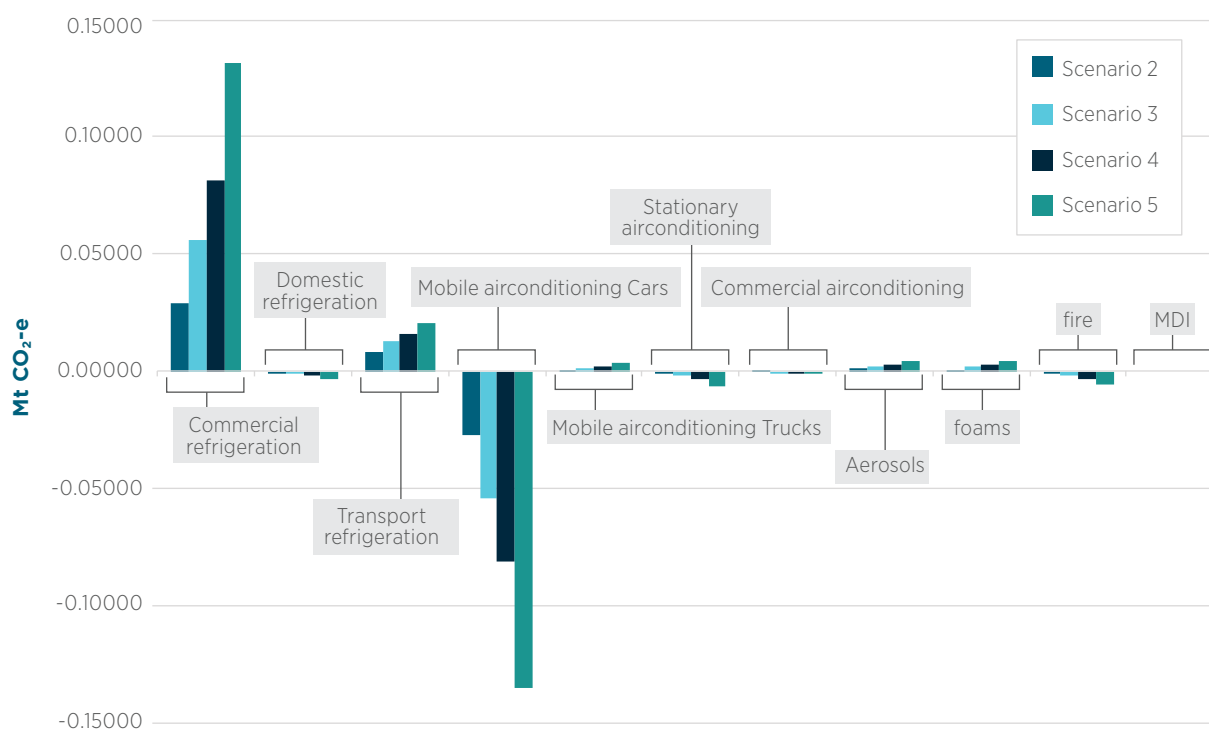

As with bulk gas allocation, the total emissions estimate was found to be insensitive to changes in assumed replenishment rates with a 50 per cent reduction in replenishment resulting in only a 0.25 per cent change in total emissions in 2008. The effects of changes to the replenishment assumptions on total emissions within the model, while minimal, are complex. The total gas allocated to equipment is unchanged under these scenarios such that when less gas is allocated to replenishment, more is available to be allocated to new equipment.

Figure 4.13 shows that emissions from commercial refrigeration increase as a result of a reduction in the general rates of replenishment as more gas is allocated to new equipment for this category. However, for domestic refrigeration, mobile air conditioning in cars and domestic stationary air conditioning the gas stocks are affected by the quantity of gas being replenished and thus, as a result of less gas being replenished, the gas bank and therefore emissions are lower for these categories.

Table 4.46 Halocarbons: results of sensitivity testing of replenishment assumptions (Mt CO₂-e)

	Replenishment assumptions				
	Base	Case 1	Case 2	Case 3	Case 4

4.8.4 Recalculations

The following recalculations have occurred since the last inventory submission:

- The adjustment of RAC equipment annual leakage rates over time according to an implied national emission factor derived from CSIRO atmospheric measurements was discontinued in order to strengthen the value of the CSIRO estimate as a tool for independent comparison, simplify the NIR methodology employed, and reduce the volatility of estimated emissions.. Equipment annual leakage rates for equipment in 2013 and earlier years were derived from Expert Group 2013; rates for 2018 and subsequent years were derived from Expert Group 2013; and a linear interpolation was applied for rates from 2014 to 2017.
- Technical corrections were made to the coding of the equipment retirement function in the HFC emission model.

Table 4.47 2.F Product Uses as Substitutes for Ozone Depleting Substances: recalculation of total CO₂-e emissions (Gg)

4.8.5 Planned improvements

The Department keeps methods and activity data under review. Enquiries were made with industry participants in developing this submission to assess the extent of recycling of HFC gas in Australia. This investigation did not indicate that significant recycling is currently occurring; this issue will be monitored to assess whether significant reuse of HFC gas in Australia occurs.

4.9 Source Category 2.G Other product manufacture and use

4.9.1 Electrical Equipment (2.G.1)

Australia has implemented the IPCC tier 2a method to estimate emissions of SF₆ from the electricity supply and distribution network.

Equation 3.16

$$\text{Total Emissions} = \text{Manufacturing Emissions} + \text{Installation Emissions} + \text{Use Emissions} + \text{Disposal Emissions}$$

Australia has chosen this method in accordance with the IPCC *good practice guidance* decision tree because:

- SF₆ is used in electrical equipment in Australia;
- This is not a key source for Australia; and
- Activity data and EFs are available from data reported under the NGER Scheme.

Country specific emission factor (use of equipment)

With the availability of facility-level leakage rates from 2010 onwards under the NGER Scheme, Australia has developed a country-specific EF for the operation of electricity supply and distribution equipment.

A base country-specific EF was estimated using data obtained from over 300 facilities reporting under the NGER System estimated consistent with the IPCC tier 3b method (IPCC GPG 3.56). This base factor is then calibrated each year from 2010 onwards in line with atmospheric SF₆ concentrations measured at the CSIRO Cape Grim monitoring station.

For the 2009 reporting year amendments were made to the *National Greenhouse and Energy Reporting (Measurement) Determination 2008*, which requires utilities and other entities to estimate their emissions from their own data using mass-balance and 'top-up' approaches.

Under these approaches, surveyed entities track their total consumption of SF₆ for refilling of equipment, the total nameplate capacity of their equipment, the quantity of SF₆ recovered from retiring equipment, and the nameplate capacity of their retiring equipment in the principle method. The approaches are consistent with those set out in the *Electricity Networks Association Industry Guideline for SF₆ Management*, ENA Doc 022-2008.

In the reporting year 2010, 15 companies, with stocks of 5.2 Mt of SF₆ as CO₂-e, elected to utilise one of the new EF methods to estimate losses, including the two largest users of SF₆ in Australia.

The weighted average emission rate derived from these 15 NGER reports was estimated at 0.0078 tonnes of SF₆ per tonne of stock of SF₆ per year.

In 2011, the average emission rate derived from these 15 NGER reporters (with stocks of 5.2 Mt in 2011) was estimated at 0.01 tonnes of SF₆ per tonne of stock of SF₆ per year.

The fluctuation in leakage rates between two reporting years is attributed to differing service intervals and equipment retirement and replacement schedules. This fluctuation was smoothed by taking a weighted average of the two years leakage rates to derive a leakage rate of 0.0089 tonnes of SF₆ per tonne of stock of SF₆ per year.

The reported EF obtained from facilities under NGER Scheme incorporates emissions from the operation of equipment and also emissions from disposal. A separate estimate of emissions from disposal is not available. Nonetheless, emissions from disposal are included with the EF from operation or use of the equipment – refer to *Energy Networks Australia, ENA Industry Guidelines for SF₆ Management*, ENA Doc 022-2008.

Calibration of annual leakage rate with atmospheric observations

Annual loss rates of SF₆ from 2010 onwards are adjusted in line with changes in atmospheric concentrations measured at the Cape Grim monitoring station in Tasmania (CSIRO 2021). CSIRO uses inverse modelling techniques to derive an estimate of national SF₆ emissions based on atmospheric measurements of SF₆ concentrations. The base annual leakage factor is indexed to the changes in a national implied emission factor given by the CSIRO national estimate divided by the national stock of SF₆.

SF₆ is considered to be an ideal gas to use inverse modelling techniques to derive national estimates, as there are no sinks for SF₆ and therefore changes in concentrations reflect changes in emissions.

Inventory uncertainty for SF₆ emissions is estimated at ±30 per cent which is comparable with uncertainty estimated for the modelled emissions by CSIRO.

The calibration of leakage rates with atmospheric observation data allows the trend in atmospheric observations to be replicated in the inventory.

Annual leakage rates applied for each inventory year from 2010 onwards are shown below. As national emission estimates derived from atmospheric observations show a degree of volatility, a 3-year average has been used to derive the adjusted annual leakage rate for each inventory year. For the most recent inventory year, as CSIRO data are not yet available, the previous inventory year's leakage rate is retained. This factor will be revised based on observation data in the next submission.

Table 4.48 Annual SF₆ leakage rates derived from CSIRO estimates

Inventory year	CSIRO national SF ₆ emissions estimate (t SF ₆)	Annual leakage rate (t SF ₆ /t stock)
2010	24	0.0075
2011	23	0.0066
2012	22	0.0062
2013	22	0.0056
2014	18	0.0054
2015	20	0.0049
2016	18	0.0048
2017	20	0.0042
2018	15	0.0040
2019 ^(a)	15	0.0040
2020 ^(a)	15	0.0040

Source: CSIRO 2021.

(a) 2019 and 2020 values not yet available – have been held constant on 2018 levels.

This factor has been applied to the total stock of SF₆ gas in the electricity supply and distribution network in accordance with the decision tree at section 1.4.

Stock of SF₆ held by electrical equipment users

Data on SF₆ stocks held by users of electrical equipment for 2009 onwards included in the National Inventory Report are taken from data gas stock data reported under the NGER Scheme.

Historical stocks of gas have been derived based on a consideration of equipment stock changes between 1972 and 2008. Critical to this process is a consideration of equipment lifetimes in Australia.

There is no comprehensive data available to the Department on the retirement of equipment using SF₆ in Australia. However, evidence on the retirements of circuit breaker stock that utilise SF₆ was obtained from data published by Transgrid, the major network in the largest State of New South Wales, in the Transgrid, Network Management Plan 2011 (February 2011). The characteristics of Transgrid's operations were considered likely to be similar to those of other large utilities in Australia and mainly reflect the operation of high voltage transmission lines.

Figure 4.14 Illustration of Transgrid’s network

Source: Transgrid Network Management Plan 2011–2016.

Confirmation of the general age profile of Transgrid’s circuit breaker assets was provided in the Transgrid *Network Management Plan 2011*, page 45.

According to Transgrid 2011 the first time SF₆ was used in equipment in Australia was in the period 1975–79.

Analysis of the change in the age profile of the stock of circuit breakers using SF₆ based on changes in the asset register between 2002 and 2010 provides a basis for an estimated retirement rate of around 0.4 per cent of the stock each year since 2003 (i.e. after equipment reached approximately 28 years). Transgrid also identified plans to phase out certain classes of circuit breakers using SF₆ over the next decade. Based on Transgrid’s announced plans (Transgrid 2011, page 59), the retirement rate was expected to increase to around 1 per cent of stock by 2019.

Figure 4.15 Age profile of Transgrid's circuit breaker assets, by type of equipment

The 2006 IPCC *Guidelines* provide additional relevant information in relation to typical equipment lifetimes. In particular, the 2006 IPCC *Guidelines* indicate that equipment lifetimes containing SF₆ are 'more than 30 to 40 years'. Providing a default factor of >35 years, the range of likely outcomes reported by the IPCC is -10 per cent +40 per cent (2006 IPCC Volume 3, Chapter 8, page 8.21) – i.e. retirement is most likely to occur within the range of 31 years to 49 years.

Taking into account the above information, the oldest equipment containing SF₆ in the Transgrid stock in 2020 was expected to be 40 years old.

Figure 4.16 Estimated stock of SF₆ in Australia (Mt CO₂-e)

Estimation of emissions of SF₆ from the manufacture of switchgear and circuit breakers in Australia

In addition to emissions from the operation and disposal of electricity supply and distribution equipment, Australia also estimates emissions associated with the manufacture of electricity supply and distribution equipment.

Many major international suppliers of electrical equipment operate in Australia – ABB, Siemens, Mitsubishi etc. Currently no data are collected under the NGER Scheme from the manufacturers of electrical equipment in Australia about their use of SF₆ or their emissions of SF₆. In addition, no information is available at this time to indicate the quantities of gas imported to fill new equipment in Australia prior to sale relative to the quantities of gas imported in pre-charged equipment.

To prepare an estimate of emissions from this source requires an assumption in relation to the proportion of pre-charged imported equipment relative to equipment charged with gas domestically using imported gas.

For these estimates it is assumed that half of all equipment used in Australia was either manufactured in Australia or that, if imported, the equipment was charged with SF₆ in Australia. To proxy this outcome, the amount of SF₆ required for charging of new equipment in Australia was assumed to be equal to half of the sum of the change in stock of SF₆ in use recorded during the year and estimated emissions from use in stock.

The IPCC 2006 does not report a default emission rate for global manufacturing. It does report factors taken from studies in Europe, which put leakage rates between 7 per cent for sealed pressure units and 8.5 per cent for closed pressure units. Much higher rates are assumed for Japan (29 per cent).

On the other hand, New Zealand reported a leakage rate associated with charging of units during manufacturing in 2009 of 0.79 per cent. The major manufacturer of this equipment in New Zealand, ABB, is also a significant supplier in Australia and, as Australian and New Zealand economies are highly integrated and reflect related political and cultural histories, it could be appropriate to consider the country-specific data from New Zealand.

Given the range of factors available, Australia has assumed that the IPCC 2006 rates identified for European closed pressure units, which lie around the mid-point of the range, are applicable in Australia from 1996 onwards and the pre-96 GPG factor of 15 per cent prior to 1996.

Time series consistency

The construction of a time series of emissions estimates requires:

- a. estimates of stocks over time;
- b. EFs over time; and
- c. emissions from disposals of equipment containing SF₆.

Time series of stocks of SF₆

Data on stocks of SF₆ are not available prior to 2009. To fill the gap, a time series of the stock of SF₆ was derived from:

- i) Data on the age profile of equipment

Data on the age profile of the circuit breaker stock using SF₆ was constructed from data on circuit breakers used by Transgrid, the major network in the largest State of New South Wales (*Transgrid, Network Management Plan 2011*, February 2011). Information was available by manufacturer, type of unit (SF₆ or oil), marquee and date of installation. SF₆ was used in equipment in Australia for the first time in the period 1975–79.

ii) Retirements

Retirements of circuit breaker stock using SF₆ were calculated from the change in the age profile of the stock based on changes in the asset register between 2002 and 2010. Retirements were estimated at around 0.4 per cent of the stock for each year since 2003 (after equipment reached approximately 28 years) with the retirement rate reaching 1 per cent of stock by 2020.

iii) Additions of new electrical equipment containing SF₆

Estimates of the additions to the stock of circuit breakers using SF₆ were determined from the change in the stock of circuit breakers and estimated retirements.

New equipment NC = observed (i.e., net) increase in the total equipment NC + decreases in the equipment NC due to retirements.

iv) Extrapolation of Transgrid age profile and management regime to the rest of Australia

The time profile of the stock of Transgrid's circuit breakers was used to derive an estimate of the stock of SF₆ held by Transgrid using the application of a constant assumed charge per circuit breaker unit. Estimates of a time series of stock of SF₆ for Australia for 1990–2008 were derived by splicing the stock of SF₆ held by Transgrid to the national stock of SF₆ held in electrical equipment in 2009 according to data obtained from the NGER Scheme. This approach is consistent with the approaches described in the IPCC Guidelines for extrapolation of data to ensure time series consistency.

Emission factors

The IPCC guidelines notes that it is not good practice to apply recently calculated EFs to leakages from earlier periods (2006 IPCC volume 3, 8.20). In the absence of country specific information, Australia has developed a time series of EFs for use of electrical equipment derived from the following assumptions:

- application of the IPCC GPG global default factor for 1990–1995 of 5 per cent (IPCC GPG 3.58);
- application of IPCC GPG global default factor for the year 2000 of 2 per cent (IPCC GPG 3.58);
- country-specific factor for 2009 onwards – 0.89 per cent adjusted according to inverse modelled estimates in CSIRO 2019;
- interpolation of EFs between the above point estimates;
- the above emission rates include disposal emissions.

In the absence of country specific information, Australia has developed a time series of EFs for manufacture or on-site filling of imported electrical equipment derived from the following assumptions:

- application of the IPCC GPG global default factor for 1990–1995 of 15 per cent (IPCC GPG 3.58);
- application of IPCC GPG global default factor for the year 2000 of 8.5 per cent per cent (IPCC 2006 Table 8.3);

The decline in leakage rates over time reflects improved awareness and training of personnel in the handling of SF₆ as reflected in industry initiatives both globally, through CIGRE, or nationally – for example as reflected in the development of an Australian Standard AS2791/1996, *Use and handling of SF₆ in high voltage switchgear and control gear* (1996) and industry guidelines as in the Energy Networks of Australia, *Industry Guideline for SF₆ Management* (2008).

Emissions

Stocks and emissions of SF₆ emissions are presented below.

Table 4.49 Stocks and emissions of SF₆

Year	Stock of SF ₆ in electrical equipment			Manufacturing of electrical equipment			Total Emissions t CO ₂ -e

Other uses of SF₆ (2.G.2)

An estimate of SF₆ emissions from other applications including eye surgery, tracer gas studies, magnesium casting, plumbing services, tyre manufacture and industrial machinery equipment has been made on the basis of a per-capita emissions value derived from the National Inventory of New Zealand. An average per-capita emission rate of 0.8 kg of SF₆ per person per year has been applied to Australia's total population to derive a time series of emissions from this source.

Australia commenced procurement of a number of Boeing E7A Wedgetail airborne early warning and control (AEWC) aircraft in 2010 with the sixth and final unit delivered in June 2014. The IPCC Guidelines note that AEWC aircraft are a potential user and emitter of SF₆ gas where this gas is used as an insulating medium in high voltage radar units. The IPCC guidelines cite an emission factor referenced in Schwarz 2005. This emission factor is based upon the Boeing E-3A aircraft operating a large rotating radar unit. Importantly, it is noted that the radar units on these aircraft operate at voltages larger than 135kv. It is this high voltage operation that necessitates the use of SF₆ to prevent flashovers in antenna conductors. It is also noted in the reference that "All other radar systems for aircraft, be it ground or aircraft radar, primary or passive, are operated at lower voltages (up to 30 kV), so that no SF₆ is necessary, oil (silicone oil) sufficing".

The Boeing E-3A aircraft first entered service in the late 1970's. By contrast, Australia's E-7A wedgetail aircraft are a newer advanced design and operate the modern Multi-Role Electronically Scanned Array (MESA) surveillance radars. These types of radar systems operate at lower voltages than the older type radar systems employed in the E-3A - <http://www.ausairpower.net/aesa-intro.html>.

Enquiries with Boeing, the manufacturer of the 737 airframe; Northrop Grumman, the manufacturer of the MESA radar and the Royal Australian Air Force who operate the aircraft have all confirmed that no SF₆ gas is used in any capacity in the Wedgetail aircraft.

N₂O from product uses (2.G.3)

Emissions of N₂O from aerosol products and anesthesia are based on production data provided by the industrial gas manufacturers (BOC and Air Liquide) up to the year 2008. From 2008 onwards, N₂O consumption is indexed to population growth. These data and the resultant emissions estimates are confidential and are included in the 2.B.2 Nitric acid production emissions.

From 2003 onwards, one of the two N₂O producing plants in Australia ceased production and imports of N₂O commenced. For 2003 onwards, N₂O emissions from product uses are estimated based on imports in addition to domestic production.

4.9.2 Uncertainties and Time Series consistency

The tier 1 uncertainty analysis in Annex 2 provides estimates of uncertainty according to IPCC source category and gas. Time series consistency is ensured by use of consistent models, model parameters and datasets for the calculations of emissions estimates. Where changes to EFs or methodologies occur, a full time series recalculation is undertaken.

4.9.3 Source specific QA/QC

Source specific QA/QC focuses on a range of measures undertaken to ensure methods, EFs and activity data are selected and applied appropriately. Section 4.9.2.1 deals with the QA/QC measures associated with the consumption of halocarbons such as independent review, mass balance, sensitivity testing and independent verification. Section 4.9.2.2 focuses on specific QA/QC measures associated with SF₆ use in electricity supply and distribution.

With limited information available on the production and import of N₂O gas for use in Australia, a per-capita factor has been derived from historical data on production and import. This factor is estimated as 0.013 kt CO₂-e/'000 persons. A comparison with other Annex-1 reporting parties shows this per capita factor to be within the range of derived per capita factors (0.00-0.02 kt CO₂-e/'000 persons).

Figure 4.17 demonstrates it is towards the upper end of the range of per-capita factor and therefore likely to lead to a conservative estimate of emissions from N₂O use.

Figure 4.17 N₂O use implied per capita emission factors for Annex 1 countries and Australia.

This source category is also covered by the general QA/QC of the greenhouse gas inventory in Chapter 1.

4.9.3.1 Source Specific QA/QC: SF₆ use in electricity supply and distribution

Australia applies four tests to consider the reasonableness of its estimates of SF₆ emissions from the electricity supply and distribution industry:

- 1) Comparison of the country specific emission factor with the IPCC default.

The IPCC GPG provides a global default factor of 2 per cent (IPCC GPG 3.57). Australia has applied this factor for 1995, while noting that the IPCC itself is somewhat cautious about the validity of these estimates presenting an uncertainty range of ±30 per cent indicating an IPCC range of 1.33 per cent – 2.6 per cent.

The *2006 IPCC Guidelines*, page 8.17, provides that it is good practice to select factors from countries with similar equipment designs and handling practices. In Australia, and based on the purchasing patterns of Transgrid, the dominant source of equipment are European manufacturers, although with an increasing supply from Japanese manufacturers.

Table 4.50 2006 IPCC Guidelines default factors for Europe and Japan

	Default	Uncertainty	Range (higher)	Range (lower)
	Tonnes of SF ₆ emissions per tonne (nameplate)	per cent	Tonnes of SF ₆ emissions per tonne (nameplate)	Tonnes of SF ₆ emissions per tonne (nameplate)
euro closed pressure	0.026	±30 per cent	0.0338	0.0182
Japan closed pressure	0.007	±30 per cent	0.0091	0.0049
euro sealed pressure	0.002	±20 per cent	0.0024	0.0016
Japan sealed pressure	0.007	±30 per cent	0.0091	0.0049

The IPCC notes that the defaults are those documented for 1995 – before any special industry actions for emission reduction were implemented (IPCC 2006, page 8.15). This makes validity of comparison for any year after 1995 difficult.

However, it can be noted that the base national factor estimated for Australia for 2010 (0.0089) – which is an average factor applied across the full range of equipment types in use in Australia (and typically sourced from Europe or Japan) – falls within the range presented in the 2006 IPCC *Guidelines* (0.0016 to 0.0338) – that should be applied for the year 1995 (and before any emission reduction actions were undertaken by industry).

Since 1995, Australia has had active programs in place to reduce emissions from this source typified by the industry action documented in Electricity Networks Association, *Electricity Networks Association Industry Guideline for SF₆ Management*, ENA Doc 022-2008.

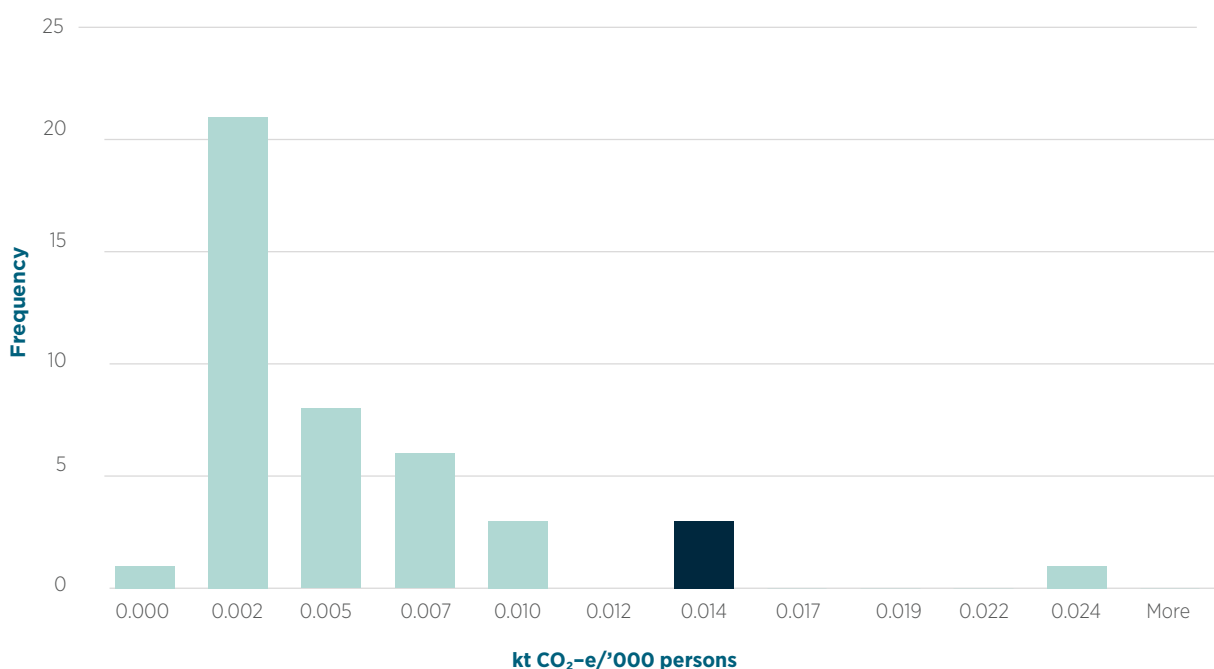

Consequently, Australia’s assessment is that the country specific base EF, 0.0089 tonnes of SF₆ emission per tonne of SF₆ stock, is consistent with the information presented by the IPCC.

2) Comparison of the country specific emission factor with the factors of similar countries.

The estimated country specific EF for Australia was compared with factors applied in other Annex-1 parties. Australia’s EF is consistent with the factors used in most Annex I parties. Sixteen other countries shared a factor in the range 0.26–0.53 reported in the histogram plot and 18 other parties had higher EFs in the group. Only 9 parties had EFs below Australia’s country specific factor.

Consequently, Australia’s national EF is considered to be consistent with those applied by other countries.

Figure 4.18 Histogram of reported product life emission factors (per cent) by Annex I parties – 2019 (Australia in marked column)

Data available for Transgrid on equipment retirements are also consistent with the retirement information of other Annex I parties of similar circumstances and recent history. Of the group of major Annex I parties from Western Europe and other OECD countries (20 countries), around seven parties have identified an estimate for emissions from disposal; five indicate that disposal is 'not occurring' while the balance do not report.

3) Assessment of the time series consistency of Australia's estimates

Australia's emission estimates are considered to be time series consistent. Checks have been made in relation to the time series of both emission estimates and the time series of stocks.

4) Assessment of the time series consistency of Australia's estimates with IPCC default growth rates

Trend data were tested for consistency with IPCC GPG expectations for growth based on global growth data. The time series of the stock of SF₆ was checked against the increase in stocks cited as a good practice default growth rate for the period 1990–1996 of 6 per cent (IPCC GPG 3.60). The calculated time series shows the stock of SF₆ in Australia grew by 7 per cent in 1996 and is comparable with IPCC default data.

4.9.4 Recalculations

No recalculations were undertaken for SF₆ as shown in Table 4.51.

4.10 Source Category 2.H Other

4.10.1 Food and beverage industry (2.H.2)

Source Category Description

The supply of CO₂ gas for use in the food and drink industry is provided from three main sources in Australia. Three ammonia producers sell a proportion of the CO₂ generated as a by-product of the ammonia production process to the food and drink industry. Gas is also obtained from two natural CO₂ wells located at Caroline in South Australia (commissioned in 1967) and Boggy Creek in Victoria (commissioned in 1995). The third source is by product CO₂ from an ethylene oxide plant located in Botany in New South Wales.

In the case of the CO₂ wells and the ethylene oxide plant, some CO₂ sold is also used for medical and other purposes (such as use in fire extinguishers). However, all CO₂ sold by these operators is reported under 2.D.2 *Food and drink*.

A small source of CO₂ emissions also derives from the use of sodium bicarbonate in food production. These emissions are also reported under 2.D. Sodium bicarbonate is a by-product of the production of soda ash.

The manufacture of beer, wine, alcoholic spirits, and bread involve the use of fermentation processes. The IPCC (1997) indicate the fermentation of sugar by industry is not considered to be a net source of CO₂ emissions, consistent with the IPCC *Guidelines*, Australia does not estimate CO₂ emissions from this source. NMVOC emissions from food and drink production, however, are included in the inventory. Production data for meat and poultry, beer and wine are obtained from ABS. Production data for sugar are obtained from ABARES (2021).

Methodology

Emissions of CO₂ from food and drink are derived based on the assumption that all CO₂ gas used is emitted in the year of production.

CO₂ generated in the production of ammonia and then captured for consumption in the food and drink industry is described in the method for the estimation of emissions from ammonia production (2.B.1). The quantity of CO₂ supplied from the single gas well is derived based on published production capacity. The quantity of CO₂ supplied from the ethylene oxide plant is derived based on the production capacity of the plant and a CO₂ EF of 0.45 tonnes of CO₂ per tonne of ethylene oxide produced taken from the Netherlands National Inventory Report (no IPCC default factor is provided and the Netherlands is the only party to report emissions from this source). It is assumed that all CO₂ generated is sold for use in food and drink production.

The method for the calculation of emissions from the use of sodium bicarbonate is provided with the method for the estimation of emissions from soda ash (2.A.4).

Emissions of NMVOCs from food and drink production are based on tier 2 methods and IPCC default EFs. Generally the methods involve multiplying the product activity level data (the amount of material produced or consumed) by an associated EF per unit of production or consumption. The NMVOC EFs used are as follows:

- Beer 0.035 (kg NMVOC/hl beverage produced);
- Red Wine 0.08 (kg NMVOC/hl beverage produced);
- White Wine 0.035 (kg NMVOC/hl beverage produced);
- Bread 1.66 (kg NMVOC/t food produced);
- Sugar 10 (kg NMVOC/t food produced); and
- Meat and Poultry 0.3 (kg NMVOC/t food produced).

4.10.2 Uncertainties and time series Consistency

The tier 1 uncertainty analysis in Annex 2 provides estimates of uncertainty according to IPCC source category and gas. Time series consistency is ensured by use of consistent models, model parameters and datasets for the calculations of emissions estimates. Where changes to EFs or methodologies occur, a full time series recalculation is undertaken.

4.10.3 Source specific QA/QC

This source category is covered by the general QA/QC of the greenhouse gas inventory in Chapter 1.

4.10.4 Recalculations since the 2019 Inventory

No recalculations were undertaken in the Other sector in this submission as shown in Table 4.53.

4.10.5 Planned improvements

Activity data and EFs will be kept under review.

Appendix 4.A Methodology applied to estimate uncertainty of CSIRO inverse modelled estimates of fluorinated gases (Category 2.F)

This Appendix responds to recommendation I.14 of the UNFCCC *Report on the individual review of the annual submission of Australia submitted in 2021* (3 March 2022).

While inverse modelled estimates of HFC gas emissions published by the CSIRO (most recent estimates set out in CSIRO 2021) are no longer used to calibrate leakage rates in Australia's National Inventory estimates for category 2.F, this information is presented here for transparency.

InTEM

The inverse modelling methodology (InTEM: Inversion Technique for Emission Modelling), used by CSIRO to derive independent estimates of Australian HFC emissions, has been developed over the past two decades at the UK Met Office (Manning et al. 2011, 2021). InTEM uses a Bayesian statistical technique with a non-negative least squares solver to find the emission distributions that produces the modelled times-series at the Cape Grim Baseline station that has the best statistical match to the observations (Manning et al. 2021).

InTEM Uncertainty

InTEM takes into account uncertainties in:

- Observations
- Prior emissions
- The Model

The observation uncertainty (σ_o) is estimated each day by repeatedly measuring the HFCs in the same tank of air. The standard deviation of these measurements is defined as the observation uncertainty for that day's observations for each gas (Manning et al. 2021).

InTEM requires the use of a prior emission distribution with associated uncertainties. The prior emissions for the HFCs are based on population distribution and have a large uncertainty (100%) to avoid over-constraining.

The model uncertainty has three parts:

- Background uncertainty (σ_b)
- Meteorological uncertainty (σ_m)
- Atmospheric variability uncertainty (σ_v)

The background uncertainty is estimated during the fitting of the baseline trend to the baseline observations. The meteorological uncertainty of each 4 hour window is proportional to the magnitude of the pollution event, with an imposed minimum uncertainty equal to the median pollution event for that gas and for that year. The third component is the atmospheric variability of the observations within a 12 hour window centred on each 4 hour InTEM sample period.

The overall model and observation uncertainty for each 4 h period (σ_t) is given by the following equation (Manning et al. 2018, 2021):

$$\sigma_t = \sqrt{\sigma_o^2 + \sigma_b^2 + \sigma_m^2 + \sigma_v^2}$$

This model and observation uncertainty is used to weight each 4-hour observation used by the inversion (i.e. the more uncertain the observations and model are for a particular 4-hour period, the less influence that observation would have on the results). The model and observation uncertainties, as well as the prior uncertainties, are also used by InTEM for calculation of the emission uncertainties.

The inversion for each 2-year inversion window is repeated 24 times omitting roughly 10% of the observations (specifically, 8 randomly-selected 5-day periods per year are omitted). The range from these repeated inversions improves the emissions uncertainty, while helping to prevent any individual pollution events from dominating the estimated emissions.

5. Agriculture

5.1 Overview

Agriculture produced an estimated 67.8 Mt CO₂-e emissions or 12.9 per cent of net national emissions (excluding *LULUCF*) in 2020 (Table 5.1).

Enteric fermentation was the main source of *Agriculture* emissions, contributing 68.2 per cent (46.2 Mt CO₂-e) of the sector's emissions. The next largest source was *agricultural soils* (18.2 per cent), followed by *manure management* (9.1 per cent). *Liming* and *urea application* contribute 4.1 per cent of the sector's emissions with *rice cultivation* and *field burning of agricultural residues* contributing the remainder (0.3 per cent).

Table 5.1 Agriculture sector CO₂-e emissions for 2020

Trends

Emissions from *Agriculture* decreased by 20.1 per cent (17.1 Mt CO₂-e) between 1990 and 2019 and decreased by 2.8 per cent (1.9 Mt CO₂-e) between 2019 and 2020 (Figure 5.1).

Enteric fermentation emissions are driven by livestock population numbers, in particular, pasture-raised beef cattle. Between 1990 and 2020 enteric fermentation emissions declined by 28.4 per cent (18.4 Mt CO₂-e). The decline in emissions in the early 1990s was principally driven by a steep fall in sheep numbers due, in large part, to the collapse of the wool reserve price scheme. The changes in flock and herd numbers reflect changing relative returns to the beef and sheep meat/wool industry and climatic conditions such as drought.

Between 2019 and 2020, emissions from *enteric fermentation* decreased by 4.1 per cent (2.0 Mt CO₂e). Drought conditions in recent years have resulted in a decline in Australian livestock numbers. The national pasture-raised beef cattle herd peaked in 2013 at 25.7 million and is now at its lowest level in the inventory time series (21.2 million in 2020), although this has been somewhat offset by the upward trend in the number of cattle finished in feedlots. Dry conditions also impacted the sheep industry, with sheep numbers in 2020 (66.7 million) the lowest in the inventory time series.

Figure 5.1 CO₂-e emissions from agriculture, 1990–2020

Figure 5.2 CO₂-e emissions from agriculture, by sub-sector, 1990–2020

Agricultural soils emissions decreased by 0.6 per cent (0.08 Mt CO₂-e) between 1990 and 2020. The long term gradual upward trend, which is the result of increasing agricultural fertiliser use and increase in retention of crop residues, was reversed between 2016 and 2019 as drought conditions saw a decrease in crop yields and fertiliser use. While remaining relatively low, *agricultural soils* emissions increased 1 per cent (0.1 Mt CO₂-e) between 2019 and 2020.

Manure management emissions decreased by 2.8 per cent (0.18 Mt CO₂-e) between 1990 and 2020 and show no clear trend. Emissions in this sector decreased by 3.3 per cent (0.21 Mt CO₂-e) between 2019 and 2020. The decrease in *manure management* emissions during this time is mainly attributable to a decrease in cattle on feed due to prolonged drought conditions across cattle producing areas, resulting in higher feed costs and accelerated destocking rates.

Emissions from *liming* and *urea application* have both increased by 1.1 Mt CO₂-e since 1990. Between 2019 and 2020 liming emissions remained unchanged, while urea application emissions increased by 0.13 Mt CO₂-e.

Emissions from *rice cultivation* in 2020 were 95.7 per cent (0.5 Mt CO₂-e) lower than in 1990 and 34.4 per cent (0.01 Mt CO₂-e) lower than in 2019. As rice cultivation in Australia is highly responsive to water availability, the trend in rice area under cultivation, and the resultant emissions, can be highly variable from year to year. The recent drought has seen a steep decline in area under rice production and subsequently yield, due to high water prices and low availability of irrigation water.

From around 2001, there was a sharp decline in rice cultivation as water resources became scarcer. The end of the millennium drought around 2009 saw rice cultivation increase again, although not to the levels observed prior to the onset of the drought. The increase in CH₄ emissions from rice cultivation observed in 2011 occurred as a result of an increase in the area of rice cultivation after the prolonged drought and water policy reform. A similar increase is projected to occur in 2021.

Emissions from *field burning of agricultural residues* decreased by 50.1 per cent (0.2 Mt CO₂-e) between 1990 and 2020, but increased by 5.3 per cent (0.01 Mt CO₂-e) between 2019 and 2020. The long-term decrease is due to a decline in stubble burning practices in Australia as the practice of stubble retention became more widespread. Another contributing factor to decreasing emissions is the decline of sugar cane burning as the industry has shifted to green cane harvesting and use of trash blankets.

5.2 Overview of source category description and methodology – Agriculture

The *Agriculture* sector includes emissions from seven sub-sectors, listed in Table 5.1.

Livestock industries produce CH₄ and N₂O emissions during feed consumption (enteric fermentation (3A)) and from animal waste products (manure management (3B)). In Australia, the principal livestock species are cattle and sheep, with breeds chosen for pasture and paddock management systems and, in many cases, in semi-arid or tropical and sub-tropical climatic conditions. As a consequence, typical animal performance tends to vary significantly from those of other Annex I countries. Intensive livestock industries also play an increasing role in Australia, specifically for dairy and beef cattle, poultry and swine.

Other agricultural sources include CH₄ emissions from rice cultivation (3C), N₂O emissions from agricultural soils (3D) and agricultural crop residues (3F), and CO₂ emissions from the application of lime (3G) and urea (3H) to agricultural soils.

Emissions from burning of tropical forests and tropical and semi-arid grasslands in Northern and Central Australia (previously reported as prescribed burning of savannas prior to the expansion of the scope of *Land Use, Land Use Change and Forestry* under the 2006 IPCC Guidelines) are reported under *Land Use, Land Use Change and Forestry*.

The Australian agriculture methodology consists of both country specific (CS) and IPCC default methodologies and emission factors (EFs) (Table 5.2).

Table 5.2 Summary of methods and EFs: Agriculture (CH₄ and N₂O)

(a) Not estimated as IPCC (2006) provides no methods or EF for this source.

(b) Not estimated as the source is considered insignificant (<0.05 per cent of national total) and data is difficult to collect (see Annex 5).

CS = country specific, IPCC = IPCC defaults, T1 = tier 1, T2 = tier 2, T3 = tier 3, NE = not estimated, NA = not applicable, IE = included elsewhere.

The *Agriculture* inventory is compiled on a State basis with State emissions totals aggregated into the national account. The inventory is compiled in this way to reduce errors associated with averaging input data across areas with large physical, climatic and management differences.

Australia has a land area of 769 million hectares which covers a wide range of climate zones, soil and vegetation types (see Section 6.2.1 for more details). These large physical differences lead to significant variability between States in such things as fuel loads for fires, the quality and availability of feed, and the performance of animals throughout the year. For example, in northern Australia there are two distinct seasons – wet and dry. During the dry season (winter-spring) the quality and availability of fodder is significantly reduced leading to weight loss in cattle, while in the southern states pasture growth and availability is lower during the colder autumn-winter months. As the climate ranges from tropical to cool, methane conversion factors for manure management systems (MMS) can also vary significantly between the States.

5.2.1 Data sources

The inventory for the *Agriculture* sector relies primarily on livestock numbers and crop production statistics from the Australian Bureau of Statistics (ABS) (census/survey data collected on 30 June in the relevant year) and data provided by industry associations (Table 5.3). There is limited activity data for the livestock categories horses, camels, buffalo, deer, goat, mules and asses, alpacas, and emus and ostriches. As such, population data is only updated every five years, when more detailed census data is provided to the ABS. Activity data used to estimate emissions are published on the AGEIS (<https://ageis.climatechange.gov.au/>).

Other primary data used in equations (liveweight, liveweight gain, pasture digestibility, allocation to MMS etc) are based on reviews of published data and expert assessments. Additional data sources are documented in Appendix 5.

Table 5.3 Summary of principal data sources for Agriculture

Agriculture sector		Activity data

3H	Urea application	Fertilizer Australia (annual)

Process for eliciting expert assessments

Given the extensive nature of most of Australia's agricultural production, there are few, if any, comprehensive State databases of information such as animal and feed characteristics. As this data is required to estimate emissions, it has been necessary to use expert assessments to determine appropriate CS information (Table 5.4). The pasture-based beef cattle and sheep categories contain a number of expert assessments, with the CS values reviewed in 1995 (documented in *Workbook for Livestock 6.1* (NGGIC 1996)) and again in 2000–01 (documented in Howden *et al.* 2002 and White 2002). In each case, consultants were used to coordinate the review. The consultants elicited expert assessments either through round table meetings or through surveys. Assessments were then compiled and agreed revised values circulated to the Expert Advisory Panels for final comment.

The consultants also undertook a number of checks on the assessments to ensure that correlated values such as seasonal liveweight, daily liveweight gain, pasture digestibility and crude protein content were internally consistent (White 2002). Expert assessments were also used in the dairy and feedlot cattle, pig and poultry categories. The data for these categories were reviewed in 2014–15 with the outcomes documented in Wiedemann *et al.* (2014) and Dairy Technical Working Group (2015).

Comparison with international data

The ABS reports agricultural data to the United Nations Food and Agriculture Organization (FAO) annually. Some divergence occurs between the activity data in the inventory CRF tables and those published by the FAO. The reasons for these differences include:

- a) Beef cattle numbers reported in the CRF differ from those reported to the FAO as the CRF tables contain ABS data adjusted for annual equivalent number of animals held in feedlots (this applies to all years). Poultry numbers differ as meat chicken data used in the inventory are annual equivalents derived from slaughter statistics rather than the static populations reported to FAO.
- b) Over the time frame of the inventory, the ABS changed the threshold of the Estimated Value of Agricultural Operations (EVAO) used to determine which agricultural operations are included in their census/survey. From 1989 to 1993 ABS used EVAO's of \$20–25,000, in comparison to \$5000 used from 1994 until 2015. From 2016, the EVAO was revised to \$40,000. To ensure time series consistency in the data, a multiplier is applied to adjust animal numbers to reflect the sub-threshold farms of the 1989–1993 and 2016 censuses. This approach has been reviewed by the ABS who deemed it to be appropriate to ensure time-series consistency in activity data.
- c) For the 2005–06 census (ABS 2007), the ABS introduced a new survey frame sourced from the Australian Taxation Office's Australian Business Register (ABR). Due to the progressive deterioration of the previous frame (based on a register of agricultural establishments maintained by ABS), the coverage of the two frames differed. To ensure time-series consistency, bridging estimates developed by ABS were used to revise animal numbers for dairy cattle, range-kept cattle, sheep and swine from 2002 to 2005.

Quantity being judged	Calculation of enteric fermentation emissions from cattle.	Revision of methods and data for feedlot cattle, swine and poultry.	Methods and EFs used to estimate emissions from inorganic fertiliser.	Manure management emissions – implementing a mass flow approach.
Logical basis for judgement	The methods for estimating methane emissions from enteric fermentation in cattle as used in the Australian national inventory were based on older data that was superseded by more recent data.	Out-of-date methods and data for these livestock categories. Changes required to reflect new international reporting requirements.	To provide CS methods and EFs that better reflect Australia's production systems and fertiliser use.	Manure from intensive livestock industries may pass through multiple treatment stages and therefore, inputs and losses should be calculated at each stage to avoid double counting.
Results (activity value, EF etc.)	There is a close relationship between dry matter intake (DMI) and methane (CH ₄) production and Charmley recommended using a unified relationship (20.7g CH ₄ /kg DMI) for dairy and beef cattle.	Several revisions to feedlot cattle, swine and poultry data and methods. For specific data please refer to document 'GHG Prediction methods for feedlots, poultry and swine'.	There is a correlation between the EFs and nitrogen use. EFs in some production systems increased with nitrogen application rates. A two component model was developed to take this into account (linear+exponential) eg. Cotton = 0.29 per cent+ (0.007(e ^{0.037} *N application rate -1)/N application rate.	A new mass flow approach was implemented which estimates the inputs (volatile solids and N) and losses (CH ₄ , N ₂ O, NH ₃) at each treatment stage. Inputs into the secondary stage take into account losses from the primary stage. This was advocated for based on research in Wiedemann <i>et al.</i> (2014).

5.3 Source Category 3.A Enteric Fermentation

5.3.1 Source category description and methodology

Methane is produced by herbivores as a by-product of enteric fermentation, a digestive process by which plant material consumed by an animal is broken down by bacteria in the gut under anaerobic conditions. A portion of the plant material is fermented in the rumen to simple fatty acids, CO₂ and CH₄. The fatty acids are absorbed into the bloodstream, and the gases vented by eructation and exhalation by the animal. Unfermented feed and microbial cells pass to the intestines.

Australia has identified enteric fermentation as a key source category using the tier 1 level and trend assessments as recommended in the 2006 IPCC Guidelines. In accordance with IPCC good practice requirements, tier 2 methods are therefore used to estimate enteric fermentation emissions from the major livestock sub-categories.

5.3.2 Cattle (3.A.1)

Pasture fed (dairy and beef)

Emissions from dairy and pasture fed beef cattle are estimated based on Charmley *et al.* (2015) who reported a close relationship between dry matter intake and methane production. The relationship of Charmley *et al.* (2015) was derived from an analysis of Australian respiration chamber data of dairy and beef (southern and northern) cattle fed diets of >70 per cent forage.

A country-specific method (Minson and McDonald 1987) based on research in Australia is used to estimate intake. Minson and McDonald (1987) derived an equation that estimates feed intake relative to liveweight and liveweight gain of cattle.

The large volumes of milk produced by dairy cattle under modern management regimes requires that the lactating cow consumes considerably more feed than an equivalent non-lactating cow. The increased energy requirements needed to produce this milk is estimated based on the average milk production per head of milking cows (Appendix 5.A.10) and the relationships presented by the Standing Committee on Agriculture (SCA 1990).

Lot-fed

Emissions from lot-fed beef cattle are estimated based on Moe and Tyrrell (1979), who related methane production to the intake of three components of the dietary carbohydrate – soluble residue, hemicellulose and cellulose. The relationship was derived from dairy cattle fed diets consisting mostly of high digestibility grains and concentrates, and high quality forages. As feedlot cattle in Australia are fed diets consisting of high digestibility grains and concentrates, the Moe and Tyrrell (1979) equation was considered the most appropriate for estimating emissions.

The IPCC (2006) simplified tier 2 method for estimating intake from growing and finishing cattle is used for feedlot cattle as it has been found to perform well against known feed intake values from commercial feedlots.

5.3.2.1 Dairy cattle (3.A.1.a)

Table 5.5 Symbols used in algorithms for dairy cattle

State (i)	Dairy cattle classes (age) (j)
1 = ACT	1 = Milking cows ^(a)
2 = Northern Territory	2 = Heifers > 1 year
3 = NSW	3 = Heifers < 1 year
4 = Queensland	4 = Bulls > 1 year
5 = Tasmania	5 = Bulls < 1 year
6 = South Australia	
7 = Victoria	
8 = Western Australia	

(a) Includes cows used for milk production but not currently lactating.

The equation presented in Minson and McDonald (1987) calculates feed intake of non-lactating cattle from liveweight and liveweight gain data. For lactating cattle the additional intake for milk production (MI_{ij}) is included to give total intake (I_{ij} kg dry matter/head/day):

$$I_{ij} = (1.185 + 0.00454W_{ij} - 0.0000026W_{ij}^2 + 0.315LWG_{ij})^2 \times MR_{ij} + MI_{ij} \quad (3A.1a_1)$$

Where W_{ij} = liveweight (kg) (Appendix 5.A.1)
 LWG_{ij} = liveweight gain (kg/day) (Appendix 5.A.2)
 MR_1 = increase in metabolic rate when producing milk (SCA 1990) 1.1 for milking and house cows and 1 for all other classes

The additional intake required for milk production (MI_{ij} kg DM/head/day) is calculated by:

$$MI_{ij} = MP_{ij} \times NE / k_l / q_{m,ij} / 18.4 \quad (3A.1a_2)$$

Where MP_{ij} = milk production (kg/head/day) from Dairy Australia State¹¹ statistics
 $NE = 3.054$ MJ net energy/kg milk (SCA 1990)
 $k_l = 0.60$ efficiency of use of metabolizable energy for milk production (SCA 1990)
 $q_{m,ij}$ = metabolizability of the diet. This is the ratio of metabolizable energy (ME) to gross energy (GE) in the diet (i.e. ME / GE). Metabolizable energy content is related to digestibility of dry matter (DMD_{ij}). So using the equation of Minson and McDonald (1987), $q_{m,ij} = 0.00795 DMD - 0.0014$; (where DMD is expressed as a per cent)

The total daily production of methane (M_{ij} kg CH_4 /head/day) is given by Charmley *et al.* (2015) as:

$$M_{ij} = 20.7 \times I_{ij} / 1000 \quad (3A.1a_3)$$

Dairy calves are generally fully weaned to pasture at 12 weeks. Until this time, calves will primarily consume milk or milk replacer, pellets and hay which results in lower emissions. The daily CH_4 production for pre-weaned dairy calves (MPW) is given in Appendix 5.A.5. Annual Australian methane production (Gg) for all classes of dairy cattle across all states can then be calculated as:

$$E = \sum_i \sum_j ((N_{ij=1,2,4} \times M_{ij=1,2,4} \times 365) + (N_{ij=3,5} \times M_{ij=3,5} \times 281) + (N_{ij=3,5} \times MPW_{ij=3,5} \times 84)) \times 10^{-6} \quad (3A.1a_4)$$

Where N_{ij} = numbers of dairy cattle in each class for each State and season
 M_{ij} = methane production (kg/head/day)
 MPW_{ij} = methane production for pre-weaned calves (kg/head/day)

5.3.2.2 Beef Cattle on Pasture (3.A.1.b)

Table 5.6 Symbols used in algorithms for beef cattle on pasture

State (i)	Regions (j)	Season (k)	Beef cattle classes (l)	Beef cattle subclass (n) ^(a)
1 = ACT		1 = Spring	1 = Bulls < 1 year	1 = Bulls < 1 year
2 = Northern Territory	2a = Alice Springs	2 = Summer	2 = Bulls > 1 year	2 = Bulls > 1 year
	2b = Barkly	3 = Autumn	3 = Cows < 1 year	3 = Cows < 1 year
	2c = Northern	4 = Winter	4 = Cows 1-2 years	4 = Cows 1-2 years
3 = NSW			5 = Cows > 2 years	5a = Cows 2-3 years
4 = Queensland	4a = High		6 = Steers < 1 year	5b = Cows > 3 years
	4b = High/moderate		7 = Steers > 1 year	6 = Steers < 1 year
	4c = Moderate/low			7a = Steers 1-2 years
	4d = Low			7b = Steers 2-3 years
5 = Tasmania				7c = Steers >3 years
6 = South Australia				
7 = Victoria				
8 = Western Australia	8a = South West			
	8b = Pilbara			
	8c = Kimberley			

(a) Beef cattle subclasses (n) only apply to NT and QLD cattle.

11 Litres of milk is multiplied by 1.03 to convert to kg of milk.

The equation presented by Minson and McDonald (1987) calculates feed intake (I_{ijkln} kg dry matter/head/day) from liveweight and liveweight gain:

$$I_{ijkln} = (1.185 + 0.00454W_{ijkln} - 0.0000026 W_{ijkln}^2 + 0.315 LWG_{ijkln})^2 \times MA_{ijkl=5} \quad (3A.1b_1)$$

Where W_{ijkln} = liveweight in kg (Appendix 5.B.1)
 LWG_{ijkln} = live weight gain in kg/head/day (Appendix 5.B.2)

Feed intake can increase by up to 60 per cent during lactation (ARC 1980). For this study, the intake of all breeding cattle was increased by 30 per cent during the season in which calving occurs and by 10 per cent in the following season, based on relationships presented in SCA (1990).

The additional intake for milk production ($MA_{ijkl=5}$) is calculated by:

$$MA_{ijkl=5} = (LC_{ijkl=5} \times FA_{ijkl=5}) + ((1-LC_{ijkl=5}) \times 1) \quad (3A.1b_2)$$

Where $LC_{ijkl=5}$ = proportion of Cows >2 lactating
 $FA_{ijkl=5}$ = feed adjustment (Appendix 5.B.5)

The total daily production of methane (M_{ijkl} kg CH₄/head/day) is given by Charmley *et al.* (2015) as:

$$M_{ijkl} = 20.7 \times I_{ijkln} / 1000 \quad (3A.1b_3)$$

To calculate beef cattle emissions it is necessary to first subtract feedlot cattle numbers from beef cattle numbers to ensure that feedlot cattle are not double counted. As feedlot cattle spend on average between 70–250 days in feedlots prior to slaughtering, an annual equivalent number is derived using an approach consistent with equation 10.1 in the 2006 IPCC Guidelines, and subtracted from beef cattle numbers.

Feedlot cattle are assumed to originate entirely from the steers > 1 year old beef cattle class. Emissions from feedlot cattle are calculated in Section 5.3.2.3.

The approach is represented in the following equation:

$$N_{ijkl} = N_{ijk(l=1, l=2, l=3, l=6, [(l=7) - \text{total feedlot numbers}])} \quad (3A.1b_4)$$

Where N_{ijkl} = numbers of non-feedlot beef cattle in each State, region, season and class
 $N_{ijk(l=1, l=2, l=3, l=6)}$ = number of cattle in State *i*, region *j*, season *k* and class *l*
 $(l=7) - \text{total feedlot numbers}$ = from Table 5.6, *l=7* corresponds with steers >1 year old. In order to calculate total beef cattle numbers in this class, total annual equivalent feedlot numbers must be subtracted from *l=7*. For WA 99 per cent of feedlot cattle are assumed to be sourced from the South-West region and the balance from the Pilbara and Kimberley.

Annual Australian methane production (Gg) for all classes of beef cattle across all seasons can then be calculated as:

$$E = \sum_i \sum_j \sum_k \sum_l \sum_n (91.25 \times N_{ijkln} \times M_{ijkln}) \times 10^{-6} \quad (3A.1b_5)$$

Where N_{ijkln} = numbers of beef cattle in each State, region, season and class
 M_{ijkln} = methane production (kg/head/day)
 91.25 = number of days in each season

5.3.2.3 Beef cattle in feedlots (3.A.1.c)

Table 5.7 Symbols used in algorithms for feedlot cattle

State (i)	Feedlot cattle classes (duration of stay) (j)
1 = ACT	1 = Domestic (70–80 days)
2 = Northern Territory	2 = Export mid-fed (80–200 days)
3 = NSW	3 = Export long-fed (200+ days)
4 = Queensland	
5 = Tasmania	
6 = South Australia	
7 = Victoria	
8 = Western Australia	

Feed intake (I_j kg dry matter/head/day) of feedlot cattle is estimated using the IPCC (2019) simplified tier 2 method.

$$I_j = W_j^{0.75} [(0.2444 \times NE_{ma,j} - 0.0111 \times NE_{ma,j}^2 - 0.472) / NE_{ma,j}] \quad (3A.1c_1)$$

Where W_j = liveweight (kg) (Appendix 5.C.1)

$NE_{ma,j}$ = Dietary net energy concentration (MJ/kg) (Appendix 5.C.2)

The equation developed by Moe and Tyrrell (1979) to predict daily methane yields (Y_j MJ CH₄/head/day) is:

$$Y_j = 3.406 + 0.510SR_j + 1.736H_j + 2.648C_j \quad (3A.1c_2)$$

Where SR_j = intake of soluble residue (kg/day)

H_j = intake of hemicellulose (kg/day)

C_j = intake of cellulose (kg/day)

SR_j , H_j and C_j are calculated from the total feed intake of the animal and the proportion of intake that is soluble residue, hemicellulose and cellulose, for each animal class (Appendix 5.C.2).

The total daily production of methane (M_j kg CH₄/head/day) is thus:

$$M_j = Y_j / F \quad (3A.1c_3)$$

Where F = 55.22 MJ/kg CH₄ (Brouwer 1965)

Methane production (Gg) for all classes of feedlot cattle across all States can then be calculated as:

$$E = \sum_i \sum_j (365 \times N_{ij} \times M_j) \times 10^{-6} \quad (3A.1c_4)$$

Where N_{ij} = numbers of feedlot cattle as an annual equivalent in each class in each State

M_j = methane production (kg/head/day)

5.3.3 Sheep (3.A.2)

Emissions from sheep are estimated based on Howden *et al.* (1994) who reported a close relationship between dry matter intake and methane production, based on an analysis of Australian respiration chamber experiments (Margan *et al.* 1985, 1987, 1988 and Graham 1964a, b, 1967, 1969). Howden *et al.* (1994) found that feed intake alone explained 87 per cent of the variation in methane production.

The Agriculture and Food Research Council (AFRC 1990) equation for intake is used here, as it corresponded well with intakes reported by State experts for seasonal feed digestibilities common in their State. The CS approach to estimating feed intake for sheep implicitly takes account of all net energy requirements for activities such as wool production, growth and grazing over large areas.

Table 5.8 Symbols used in algorithms for sheep

State (i)	Season (j)	Sheep classes (k)
1 = ACT	1 = Spring	1 = Rams
2 = Northern Territory	2 = Summer	2 = Wethers
3 = NSW	3 = Autumn	3 = Maiden ewes (intended for breeding)
4 = Queensland	4 = Winter	4 = Breeding ewes
5 = Tasmania		5 = Other ewes
6 = South Australia		6 = Lambs and hoggets
7 = Victoria		
8 = Western Australia		

Potential intake is determined largely by body size and the proportion of the diet that is able to be metabolised by the animal. Potential intake (PI_{ijk} kg DM/head/day) is given by AFRC (1990) as:

$$PI_{ijk} = (104.7 q_{m,ijk} + 0.307 W_{ijk} - 15.0) W_{ijk}^{0.75} / 1000 \quad (3A.2_1)$$

Where W_{ijk} = liveweight (kg) (Appendix 5.D.1)

$q_{m,ijk}$ = metabolisability of the diet. This is the ratio of metabolisable energy (ME) to gross energy (GE) in the diet (i.e. ME / GE). Metabolisable energy content is related to digestibility of dry matter (DMD_{ijk}) so, using the equation of Minson and McDonald (1987), $q_{m,ijk} = 0.00795 DMD - 0.0014$ (DMD is expressed as a per cent)

The potential or maximum intake of feed by sheep occurs when feed is abundant and of high quality. However, the actual feed intake of animals is often less than the potential intake. This can be caused by many factors, including through low feed availability. Relative intake is defined as the proportion of potential intake that the animal will consume. The relative intake (RI_{ijk}) related to feed availability is given by White *et al.* (1983) as:

$$RI_{ijk} = 1 - \exp(-2(DMA_{ijk})^2) \quad (3A.2_2)$$

Where DMA_{ijk} = dry matter availability (t/ha) (Appendix 5.D.3)

Note: Actual feed intake will be less than potential intake only when feed availability is less than 1.63 tonnes/ hectare. The actual intake (I_{ijk} kg DM/head/day) of a sheep is thus:

$$I_{ijk} = PI_{ijk} \times RI_{ijk} \times MA_{ijk=4} \quad (3A.2_3)$$

Where $MA_{ijk=4}$ = additional intake factor for milk production

Feed intakes can increase by up to 60 per cent during lactation (ARC 1980). For emissions estimates, the intake of all breeding ewes was assumed to increase by 30 per cent during the season in which lambing occurs, based on relationships presented in SCA (1990).

The additional intake for milk production ($MA_{ijk=4}$) is calculated by:

$$MA_{ijk=4} = (LE_{ijk=4} \times FA_{ijk=4}) + ((1-LE_{ijk=4}) \times 1) \quad (3A.2_4)$$

Where $LE_{ijk=4}$ = proportion of breeding ewes lactating, calculated as the annual lambing rates x proportion of lambs receiving milk in each season (Appendix 5.D.6)

$FA_{ijk=4}$ = feed adjustment (assumed to be 1.3)

Methane production (M_{ijk} kg/head/day) is calculated using daily intake figures (I_{ijk}) via the relationship of Howden *et al.* (1994):

$$M_{ijk} = I_{ijk} \times 0.0188 + 0.00158 \quad (3A.2_5)$$

Annual methane production (Gg) of Australian sheep is calculated as:

$$E = \sum_i \sum_j \sum_k (91.25 \times N_{ijk} \times M_{ijk}) \times 10^{-6} \quad (3A.2_6)$$

Where N_{ijk} = numbers of sheep in each class for each season and State

M_{ijk} = methane production (kg/head/day)

5.3.4 Swine (3.A.3)

Swine are non-ruminant animals, and convert a smaller proportion of feed energy intake into methane than ruminants. Whittemore (1993) suggested the output of methane by a 60 kg swine is about 0.2 MJ/day.

Assuming that on average, a 60 kg swine consumes 1.95 kg DM/day of a diet containing 18.6 MJ GE/kg, the gross energy (GE) intake was 36.3 MJ GE. Thus swine would convert around 0.6 per cent of gross energy into methane. Other values in the literature suggest methane conversions of 1.2 per cent of GE (Christensen and Thorbek 1987), 0.6 to 0.8 per cent of GE (Moss 1993) and 0.4 per cent of GE (Kirchgessner *et al.* 1991). A methane conversion of 0.7 per cent of GE intake is used for Australia.

Table 5.9 Symbols used in algorithms for swine

State (i)	Swine classes (j)
1 = ACT	1 = Boars
2 = Northern Territory	2 = Sows
3 = NSW	3 = Gilts
4 = Queensland	4 = Others
5 = Tasmania	
6 = South Australia	
7 = Victoria	
8 = Western Australia	

The relationship for enteric fermentation in swine gives the total daily production of methane (M_{ij} kg CH₄/head/day) as:

$$M_{ij} = I_{ij} \times 18.6 \times 0.007 / F \quad (3A.3_1)$$

Where I_{ij} = feed intake (kg DM/day) (Appendix 5.E.1)
 F = 55.22 MJ/kg CH₄ (Brouwer 1965)
 18.6 = MJ GE/kg feed DM

The annual production of methane (Gg) for all classes of swine is calculated as:

$$E = \sum_i \sum_j (N_{ij} \times M_{ij} \times 365) \times 10^{-6} \quad (3A.3_2)$$

Where N_{ij} = the number of swine in each class for each State
 M_{ij} = methane production (kg/head/day)

5.3.5 Other livestock (3.A.4)

The contribution of other livestock to total methane production is comparatively small. A simplified methodology based on the IPCC (2006) tier 1 method is followed, using aggregated numbers of the various livestock types and an annual methane emissions factor. The annual EFs are mostly based on IPCC 2006 defaults (Table 5.11).

The methane EFs for buffalo and emus/ostriches follow IPCC (2019), which is based on the latest internationally-assessed science. The Asian buffalo factor was adopted as most buffalo in Australia originated from Asia and are found in the Northern Territory, which experiences similar monsoonal climates to parts of Asia. No default value was provided in IPCC (2006) for emus/ostriches, therefore the IPCC (2019) factor is the best available data.

Consistent with decision 24/CP.19 (Annex I.E, para 10), this country-specific approach draws on IPCC 2019 to the extent it is better able to reflect Australia's situation than IPCC 2006. The introduction of the new estimation approaches has improved the accuracy and completeness of Australia's inventory. EFs for other livestock species were not revised in IPCC 2019.

Table 5.10 Symbols used in algorithms for other livestock

State (i)	Other livestock types (j)	Digestive type
1 = ACT	1 = Buffalo	ruminant
2 = Northern Territory	2 = Goats	ruminant
3 = NSW	3 = Deer	ruminant
4 = Queensland	4 = Camels	quasi-ruminant
5 = Tasmania	5 = Alpacas	quasi-ruminant
6 = South Australia	6 = Horses	non-ruminant (equine)
7 = Victoria	7 = Mules/asses	non-ruminant (equine)
8 = Western Australia	8 = Emus/ostriches	non-ruminant
	9 = Poultry	non-ruminant

By applying the EF to the number of each species in each State, total methane production (Gg) from the enteric fermentation of minor livestock types can be calculated as follows:

$$E = \sum_i (N_{ij} \times M_j \times 10^{-6}) \quad (3A.4_1)$$

Where N_{ij} = numbers of other livestock types in each State
 M_j = methane EF (kg/head/year) (Table 5.11)

Table 5.11 Other livestock – enteric fermentation EFs (kg CH₄/head/year)

Livestock type	EF	Source
Buffalo	76	IPCC (2019)
Goats	5	IPCC (2006)
Deer	20	IPCC (2006)
Camels	46	IPCC (2006)
Alpacas	8	IPCC (2006)
Horses	18	IPCC (2006)
Mules/asses	10	IPCC (2006)
Emus/ostriches	5	IPCC (2019)
Poultry	NE	not estimated by IPCC

5.3.6 Uncertainties and time series consistency

A quantitative assessment of uncertainty was undertaken and uncertainties for enteric fermentation were estimated to be in the order of 25 per cent. Further details on the analysis are provided in Annex 2.

Time series consistency is ensured by using consistent methods and full recalculations in the event of any refinement to methodology. See Section 5.2.1 regarding how changes to data collection methods by the Australian Bureau of Statistics have been addressed to ensure time series consistency of livestock numbers, and reasons for differences in beef cattle and poultry populations with published FAO data.

5.3.7 Source specific QA/QC

5.3.7.1 Activity data

The Australian Bureau of Statistics (ABS) is the national statistical agency of Australia and is the key provider of activity data for this source category. ABS has in place a range of quality assurance-quality control procedures associated with survey design, data input and consistency checks on the survey results and the aggregated values. Sampling errors are also evaluated.

Changes in the trends of activity data are also monitored in the inventory, to ensure the drivers of change can be explained by factors such as economic or climatic variability. This source category is also covered by the general QA/QC procedures detailed in Chapter 1.

Inverse modelling of cattle and sheep populations were undertaken to ensure consistency with reported populations. These studies showed no apparent bias in the sheep numbers (Howden 2001) but possible differences in cattle numbers in the order of 3–4 per cent (Howden and Barrett 2003). It is important to note that, with the limited datasets available for this study, the parameter solutions were non-unique and it is possible that there were no systemic differences in the numbers. Given the size of the possible differences and the inherent uncertainty in animal numbers it was agreed with ABS to incorporate this information into the uncertainty estimates rather than adjust activity data.

5.3.7.2 Implied EFs

As CS tier 2 methods are used to estimate emissions from cattle, sheep and swine, the IEFs have been compared with values in the 2006 IPCC Guidelines and the IPCC 2019 Refinement (Table 5.12). The IEFs for pasture-based beef cattle and swine are generally consistent with the IPCC values.

The dairy cattle IEF is similar to the IPCC 2019 value for Oceania (93 kg CH₄/head/year). Differences with IPCC EFs are due to the use of a more detailed age and animal class structure for Australia's dairy and beef cattle herds. The feedlot cattle IEF differs due to CS feed intakes (Section 5.3.7.3).

The lower IEFs for sheep primarily reflect the inclusion of an age structure in the Australian method (Table 5.8), and the use of actual intake as a proportion of potential intake to incorporate the likelihood of low feed quality and/or availability (Section 5.3.3), which impacts upon the methane conversion rate (Section 5.3.7.4).

Table 5.12 Implied EFs – enteric fermentation (kg CH₄/head/year)

Livestock type	Australia	IPCC 2006	IPCC 2019
Dairy cattle	93	90	93
Beef cattle – pasture	51	60	63
Beef cattle – feedlot	67	60	63
Sheep	6.8	8	5 or 9
Swine	1.6	1.5	1 or 1.5

Sources: IPCC 2006 and IPCC 2019. EFs shown are for developed countries and/or Oceania.
2019 EFs for sheep and swine vary due to disaggregation by low or high productivity systems.

5.3.7.3 Feed intake

As Australia uses CS tier 2 methods for estimating feed intakes, these values have been compared with average intakes reported by other Parties.

Cattle

For dairy cattle, average herd intakes are within the range reported by other Parties (Table 5.13). The intakes of Australian dairy cattle are in the order of 1–3 per cent of live weight (range from 1.5 to 3.16 per cent) as recommended by the IPCC (2006).

Comparison of intakes for beef cattle between Parties is complicated as animals kept under feedlot conditions have not been reported separately from pasture-based animals, as is undertaken in the Australian inventory. The average herd intake for pasture-based animals is within the range reported by other Parties, while that for lot-fed animals is higher (Table 5.13).

Intake estimates for feedlot cattle have been based on the IPCC feed intake model, which was verified by comparison with industry practices. Intakes range from 2–2.1 per cent of live weights. Gross energy intake (GEI) for feedlot cattle was predicted using a diet GE of 19.2 MJ/kg DM based on the proportions of carbohydrate, protein and fat.

Table 5.13 Average herd intake (MJ GEI/head/day)

Livestock type	Australia		Other Parties	
	Range	Mean	Range	Mean
Dairy cows (dairy herd)	206–249	231	192–404	311
Non-dairy cattle			112–194	139
Beef cattle – pasture	116–136	124		
Beef cattle – feedlot	200	200		
Sheep	13–20	17	14–51	23

Source: Other Parties' herd intake from UNFCCC locator tool

Sheep

The CS method used to estimate intake from Australian sheep produces lower average intakes than those reported by other Parties (Table 5.13). However, an analysis of intake as percentage of liveweight shows that intakes are in the order of 1–3 per cent (range from 1.0 to 2.7 per cent) as recommended by IPCC (2006).

In Australia, actual feed intake is often less than potential intake due to low feed availability. The Australian method calculates the proportion of the potential intake that the animal will actually consume (potential intake is restricted when feed availability is less than 1.63 tonnes/hectare). Restricted feed conditions generally occur in one or more seasons in all States, with animals experiencing weight loss over the season. When intakes are not limited, estimated intakes (average 20 MJ/day) are similar to levels reported by other Parties.

5.3.7.4 Methane conversion rates

As Australia uses CS methods for estimating methane emissions, methane conversion rates (Y_m) have been compared against IPCC values.

Cattle

The IPCC (2006) indicates that animals fed diets containing 90 per cent concentrates should use Y_m 3.0 per cent. The Australian methodology for feedlot cattle accounts for the different proportion of grain and forage in diets, which are lower than the 90 per cent concentrates. This results in estimated conversion rates of 4.9–5.2 per cent or an average of 183 g CH_4 /head/day. Kurihara *et al.* (1999, corrected by Hunter 2007) found similar conversion rates (5.6 per cent) for cattle fed on high grain (75 per cent) plus lucerne diets, measured using calorimetry chambers. Open path laser measurements of methane (enteric and manure) from Australian feedlots by McGinn *et al.* (2008) and Loh *et al.* (2008) have estimated enteric fermentation emissions of 161 g/head/day.

The conversion rates for dairy and beef cattle on pastures (6.1–6.2 per cent) are also consistent with IPCC (2019) values (Dairy cattle: 5.7–6.5 per cent, beef cattle on pasture: 6.3–7.0 per cent).

Sheep

The methodology for estimating emissions from sheep has been independently verified. Leuning *et al.* (1999) found close agreement between the methane emissions estimated by the inventory methods and direct field measurements made using micrometeorological mass-balance and SF_6 tracer techniques. Using the inventory methods and default livestock characterisation, Leuning *et al.* (1999) estimated CH_4 emissions to be 12.6 g/head/day compared with 11.9 (± 1.5) and 11.7 (± 0.4) g/head/day measured by the mass-balance and SF_6 tracer techniques respectively. When the experimental livestock characterisation was used with inventory methods, CH_4 emissions were estimated to be 11.1 g/head/day.

In addition, an analysis of Australian respiration chamber experiments by Williams and Wright (2005) showed a very similar relationship between methane output and dry matter intake ($\text{CH}_4 = 0.0187 \times \text{DMI} - 0.0003$) to that reported in Howden *et al.* (1994) ($\text{CH}_4 = 0.0188 \times \text{DMI} + 0.00158$).

The herd average Ym for Australian sheep is 6.2 per cent which is within the range of the IPCC (2019) value (6.7 per cent).

External Review

Comprehensive expert peer review of the methodologies, activity data and livestock characterisation data were conducted for sheep in 2000–01; dairy and feedlot cattle, swine and poultry in 2014; and QLD/NT beef cattle on pastures in 2015 (Bray *et al.* 2015). These reviews involved agricultural experts from industry, government and academia.

5.3.8 Recalculations since the 2019 Inventory

There were no recalculations affecting this subsector in the 2022 submission.

5.3.9 Source specific planned improvements

The inventory improvement plan for the agriculture sector identified areas which require updating or review over the next few years. Areas for improvement are identified through the UNFCCC expert reviews, domestic QA/QC processes or the expected availability of new data or empirical studies which could improve accuracy of the inventory.

For enteric fermentation the following areas have been identified for review and/or change:

1. *Beef cattle pasture and feedlot methods and parameters* – review methods, parameters and activity data used to estimate enteric fermentation emissions from beef cattle to support Livestock Emission Reduction Roadmap implementation of potential emission reductions associated with feed supplements. These activities are being led by the Australian red meat industry as part of its ambition to be carbon neutral by 2030.
2. *Sheep methods and parameters* – review methods and parameters used to estimate enteric fermentation emissions from sheep, using recent published data such as from the Reducing Emissions from Livestock Research Program.
3. *Feed and animal characteristics* – As these characteristics can change as industry practices change over time, the current values need to be reviewed periodically.

5.4 Source Category 3.B Manure Management

5.4.1 Source category description and methodology

Methane is produced from the decomposition of organic matter remaining in manure under anaerobic conditions. These conditions occur when large numbers of animals are managed in a confined area, where manure is typically stored in large piles or lagoons.

Direct N₂O emissions from MMS can occur via combined nitrification and denitrification of ammoniacal nitrogen contained in the wastes. The amount released depends on the systems and duration of waste management. Indirect N₂O emissions occur via runoff and leaching, and the atmospheric deposition of N volatilised from the MMS.

As manure from intensive livestock industries may pass through multiple treatment stages, Australia applies a tier 3 mass flow approach to estimating emissions whereby the volatile solid and nitrogen inputs and losses are estimated at each treatment state. Inputs into the secondary treatment stage take into account losses from the primary stage (see Figure 5.3).

Subscripts for the algorithms are the same as used for calculating enteric fermentation (Tables 5.5–5.10) with an additional MMS component (Table 5.14).

Figure 5.3 Mass flow method of estimating manure management emissions – feedlot cattle example

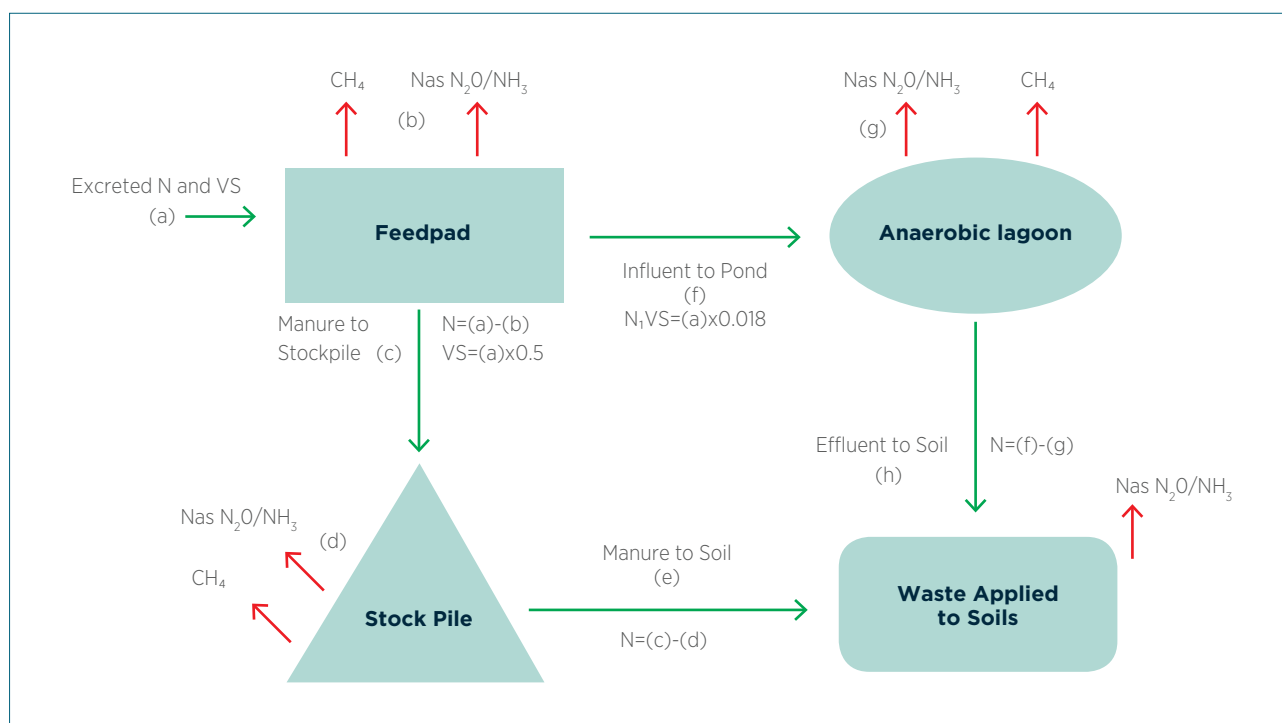

Table 5.14 Additional symbols used in algorithms for manure related emissions

Manure Management Systems (MMS)	
1 = Anaerobic lagoon	8 = Deep litter
2 = Liquid systems	9 = Pit storage
3 = Daily spread	10 = Poultry manure with bedding
3a = Sump and dispersal system	11 = Poultry manure without bedding
3b = Drains to paddock	11a = Belt manure removal
4 = Solid storage	11b = Manure stored in house
5 = Drylot (feed pad)	12 = Direct processing
6 = Composting (passive windrow)	13 = Direct application
7 = Digester/covered lagoons	14 = Pasture range and paddock

5.4.1.1 Methane

Methane emissions from livestock into MMS

Methane production from the manure of dairy cattle, feedlot cattle, swine and poultry is calculated based on the volatile solids entering the MMS, and CS and default IPCC methane conversion factors (MCF). An integrated methane conversion factor (iMCF) has been calculated taking into account the proportion of manure managed in each system, the MCF of each system, and VS losses from earlier stages in the MMS. The specific allocations of manure to the different MMS, the VS loss assumptions, and the applied MCFs are documented in Appendix 5.

Manure management emissions for feedlot beef, swine and poultry exceed 100 per cent in the allocation of MMS, as manure from intensive livestock industries may pass through multiple treatment stages. The same manure is allocated to multiple manure management system categories in these cases. For example, 100 per cent of the volatile solids will first pass through a primary system, such as a feed pad. The same manure will then pass through a secondary treatment, e.g. composting, and then through to a tertiary treatment such as an effluent pond.

Methane emissions from livestock onto pasture, range and paddock (PRP)

There are two components to methane emission estimates from range-kept livestock (e.g. pasture-based beef cattle, sheep, goats etc.):

- Emissions from dung deposited onto PRP
- Emissions from dung deposited into constructed ponds/anaerobic lagoons

The proportion of manure allocated to anaerobic lagoons is five per cent of total PRP manure. This fraction is calibrated to the estimated difference between methane emissions from constructed ponds servicing livestock and those servicing crop production, as reported in Grinham *et al.* (2018) and Ollivier *et al.* (2019), and assuming that this difference is wholly attributable to manure from livestock. Details of these calculations and total emissions for the source (farm dams) are given in *Wetlands* (Section 6.10 – Volume 2 of the NIR).

Country specific factors used to calculate methane emissions from pasture-based livestock are shown in Table 5.15, primarily from IPCC (2019). A default VS excretion rate for Oceania was not provided in IPCC (2006) so the update has been used, as it is based on the latest internationally-assessed science as reported in IPCC (2019). Methane EFs have been further disaggregated in 2019 to enable different factors to be used for the different MMS. The *2019 Refinement to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories* (IPCC 2019) informed improvements to Australia's country-specific emission estimation approaches consistent with decision 24/CP.19 (Annex I.E, para 10, *Revision of the UNFCCC reporting guidelines on annual inventories for Parties included in Annex I to the Convention*).

Table 5.15 Factors used to calculate CH₄ emissions from pasture-based livestock

Factor type and units	Factor	Source
VS excretion rate for other cattle – Oceania (1000 kg animal mass/day)	8.7	CS, IPCC 2019
TAM for cattle (Typical Animal Mass – kg)	352.4	derived from average Australian pasture-based cattle liveweights across all cattle classes
CH ₄ EF for PRP (g CH ₄ kg VS ⁻¹ for all animals, high and low productivity systems)	0.6	CS, IPCC 2019
CH ₄ EF for uncovered anaerobic lagoons (g CH ₄ kg VS ⁻¹ for non-dairy cattle in low productivity systems, in warm climate zones)	69.7	CS, IPCC 2019

Annual volatile solid excretion (kg VS/animal/year) is calculated as:

$$VS = (VS \text{ excretion rate} \times TAM/1000) \times 365 \quad (3B_a)$$

To calculate weighted EFs for PRP and lagoons, the CH₄ EFs in Table 5.15 are multiplied by the annual VS excretion rate. Resulting factors are:

- EF (PRP) = 0.67 kg CH₄/head/year
- EF (lagoon) = 78.00 kg CH₄/head/year

A combined weighted IEF (kg CH₄/head/year) is calculated as:

$$\text{Weighted IEF} = (\text{EF (PRP)} \times \text{PRP share (95\%)}) + (\text{EF (lagoon)} \times \text{lagoon share (5\%)}) \quad (3B_b)$$

The revised factor (4.54 kg CH₄/head/year) now places Australia's IEF within the range of other Annex 1 IEFs (see Figure 5.4).

The weighted IEF is then converted from kg CH₄/head/year to kg CH₄/kg DM manure for temperate and warm climatic conditions, using the proportion change between the new combined weighted IEF (4.54) and the CH₄ IEF reported for beef cattle pasture in NIR 2017 Volume 1, Table 5.16 (0.02 kg CH₄/head/year). The revised EFs are:

$$\text{EFW} = 0.012 \text{ kg CH}_4/\text{kg DM manure}$$

$$\text{EFT} = 0.003 \text{ kg CH}_4/\text{kg DM manure}$$

Where EFW = the EF for methane from manure in warm climates
EFT = the EF for methane from manure in temperate climates

EFW and EFT are then used to calculate daily CH₄ emissions (kg) per cattle class and state, using Equation 3B.1 b_1 in Section 5.4.3.1.

5.4.1.2 Nitrous oxide

Nitrogen excretion from cattle, sheep, swine, and poultry are estimated using CS tier 2 mass balance approaches where N excretion = N input – N retention. For other livestock, CS excretion rates are applied. The N₂O EF and volatilisation factors are based on a combination of IPCC (2006) default and CS values.

Where multiple manure treatment stages occur, an integrated nitrous oxide EF (iNOF) and an integrated volatilisation factor (iFracGASM_{MMS}) have been calculated taking into account the proportion of manure managed in each system, the N₂O EF and FracGASM_{MMS} of each system, and N losses from earlier stages in the MMS (see Appendix 5).

To estimate atmospheric deposition emissions, CS EFs are used. As the highest ammonia deposition rates (kg/ha) are found within a few hundred meters of the emission source, the fertiliser EFs of neighbouring production systems were considered to provide a more accurate estimate of emissions than the IPCC default EF. While the majority of volatilised N is advected away from the MMS, it undergoes significant dilution and is deposited to the wider landscape at very low rates (Dr Matt Redding, per. comm., QLD DAFF, 2014).

A CS FracLEACH value is used to calculate N that is lost through leaching and runoff associated with manure management, which is based on the latest internationally-assessed science, as reported in IPCC (2019).

The 2019 Refinement to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories (IPCC 2019) informed improvements to Australia's country-specific emission estimation approaches consistent with decision 24/CP.19 (Annex I.E, para 10, *Revision of the UNFCCC reporting guidelines on annual inventories for Parties included in Annex I to the Convention*).

Consistent with decision 24/CP.19 (Annex I.E, para 10), this country-specific approach draws on IPCC 2019 to the extent the revised factor incorporates results from recent studies in Australia and New Zealand, that are better able to reflect Australia's situation than the IPCC 2006. The introduction of the new estimation approaches has improved the accuracy and completeness of Australia's inventory.

5.4.2 Dairy cattle (3.B.1.A)

5.4.2.1 Methane

Dairy cattle are generally kept in higher rainfall areas than other Australian livestock. This, and the disposal of excreta washed from milking sheds, gives opportunities for the generation of methane. However, only a small fraction of the potential methane emissions appear to be released. Williams (1993) measured methane production from dairy cattle manure under field conditions in Australia and found that only about 1 per cent of the methane production potential was achieved. This is higher than the IPCC (2019) value of 0.47 per cent.

Methane from manure is formed from the organic fraction of the manure (volatile solids). Volatile solid production for dairy cattle (VSy kg/head/day) was estimated using the data developed to calculate enteric methane production as this included information on intakes and dry matter digestibility. For dairy cattle, volatile solids were calculated as:

$$VS_{ij} = (I_{ij} \times (1 - DMD_{ij}) + (0.04 \times I_{ij})) \times (1 - A) \quad (3B.1a_1)$$

Where I_{ij} = dry matter intake, calculated in Section 5.3.2.1
 DMD_{ij} = dry matter digestibility expressed as a fraction (Appendix 5.A.4)
 A = ash content expressed as a fraction (assumed to be 8 per cent of faecal DM)

Methane production from manure (M_{ij} kg/head/day) is then calculated as:

$$M_{ij} = VS_{ij} \times B_o \times iMCF_i \times \rho \quad (3B.1a_2)$$

Where B_o = emissions potential - 0.24m³ CH₄/kg VS (IPCC 2019)
 $iMCF_i$ = integrated methane conversion factor (Appendix 5.A.6)
 ρ = density of methane (0.6784 kg/m³) - Taken from the *National Greenhouse and Energy Reporting (Measurement) Determination 2008*

Methane produced by pre-weaned calves (MPW) is given in Appendix 5.A.5. The annual methane production (Gg) from manure of dairy cattle is calculated as:

$$Total = \sum_i \sum_j ((N_{ij=1,2,4} \times M_{ij=1,2,4} \times 365) + (N_{ij=3,5} \times M_{ij=3,5} \times 281) + (N_{ij=3,5} \times MPW_{ij=3,5} \times 84)) \times 10^{-6} \quad (3B.1a_3)$$

Where N_{ij} = numbers of dairy cattle in each State, class and season
 M_{ijk} = methane production (kg/head/day)
 MPW_{ij} = methane production for pre-weaned calves (kg/head/day) (Appendix 5.A.5)

5.4.2.2 Direct nitrous oxide emissions

The methodology for calculating the excretion of nitrogen from dairy cattle makes use of the following algorithms to calculate crude protein input (CPI_{ij}) and N retention (NR_{ij}), and from these the output of nitrogen in faeces and urine.

The crude protein intake CPI_{ij} (kg/head/day) of dairy cattle is calculated thus:

$$CPI_{ij} = I_{ij} \times CP_{ij} \quad (3B.1a_4)$$

Where I_{ij} = dry matter intake (kg/day) as calculated in Section 5.3.2.1

CP_{ij} = crude protein content of feed intake expressed as a fraction (Appendix 5.A.4)

The amount of nitrogen retained by the body (NR_{ij} kg/head/day) is calculated as the amount of nitrogen retained in milk and body tissue such that:

$$NR_{ij} = \frac{(0.032 \times MP_{ij} / 6.38) + \{0.212 - 0.008(L_{ij} - 2) - [(0.140 - 0.008(L_{ij} - 2)) / (1 + \exp(-6(Z_{ij} - 0.4)))]\} \times (LWG_{ij} \times 0.92)}{6.25} \quad (3B.1a_5)$$

Where MP_{ij} = milk production in kg/head/day (Appendix 5.A.10)

L_{ij} = Intake relative to that needed for maintenance. Calculated as actual intake divided by maintenance intake (i.e. intake of non-lactating animal with LWG set to zero calculated by equation 3A.1a_1)

Z_{ij} = relative size - (liveweight / standard reference weight (Appendix 5.A.1 and 5.A.3))

LWG_{ij} = liveweight gain (kg/day) (Appendix 5.A.2)

Nitrogen excreted in faeces (F_{ij} kg/head/day) is calculated using functions developed by SCA (1990) and Freer *et al.* (1997), as the indigestible fraction of the undegraded protein from solid feed and the microbial crude protein plus the endogenous faecal protein, such that:

$$F_{ij} = \{0.3(CPI_{ij} \times (1 - [(DMD_{ij} + 10) / 100])) + 0.105(ME_{ij} \times I_{ij} \times 0.008) + (0.0152 \times I_{ij})\} / 6.25 \quad (3B.1a_6)$$

Where DMD_{ij} = dry matter digestibility expressed as a per cent (Appendix 5.A.4)

ME_{ij} = metabolizable energy (MJ/kg DM) calculated as: $0.1604 DMD_{ij} - 1.037$ (Minson and McDonald 1987)

I_{ij} = dry matter intake (kg/day)

Nitrogen excreted in urine (U_{ij} kg/head/day) is calculated by subtracting NR_{ij} , F_{ij} and dermal protein loss from nitrogen intake such that:

$$U_{ij} = (CPI_{ij} / 6.25) - NR_{ij} - F_{ij} - [(1.1 \times 10^{-4} \times W_{ij}^{0.75}) / 6.25] \quad (3B.1a_7)$$

Where W_{ij} = liveweight (Appendix 5.A.1)

Pre-weaned dairy calves are usually removed from their mothers and receive milk or milk replacer and feed pellets. The nitrogen excreted in faeces (FPW) and urine (UPW) of pre-weaned calves is given in Appendix 5.A.5.

The total annual faecal (AF_{ij} Gg) and urinary (AU_{ij} Gg) nitrogen excreted is calculated as:

$$AF_{ij} = \sum_j ((N_{ij=1,2,4} \times F_{ij=1,2,4} \times 365) + (N_{ij=3,5} \times F_{ij=3,5} \times 281) + (N_{ij=3,5} \times FPW_{ij=3,5} \times 84)) \times 10^{-6} \quad (3B.1a_8a)$$

$$AU_{ij} = \sum_j ((N_{ij=1,2,4} \times U_{ij=1,2,4} \times 365) + (N_{ij=3,5} \times U_{ij=3,5} \times 281) + (N_{ij=3,5} \times UPW_{ij=3,5} \times 84)) \times 10^{-6} \quad (3B.1a_8b)$$

Where N_{ij} = the number of dairy cattle in each State and class

The annual faecal ($FN_{ij,MMS}$ Gg) and urinary ($UN_{ij,MMS}$ Gg) nitrogen in the different MMS can then be calculated as follows:

$$FN_{ij,MMS} = (AF_{ij} \times MMS) \quad (3B.1a_9a)$$

$$UN_{ij,MMS} = (AU_{ij} \times MMS) \quad (3B.1a_9b)$$

Where MMS = the fraction of nitrogen that is managed in the different MMS (Appendix 5.A.8)

The total emissions of nitrous oxide from the different MMS can then be calculated as follows:

$$Faecal_{ij,MMS} = (FN_{ij,MMS} \times EF_{(MMS)} \times C_g) \quad (3B.1a_10a)$$

$$Urine_{ij,MMS} = (UN_{ij,MMS} \times EF_{(MMS)} \times C_g) \quad (3B.1a_10b)$$

$$Total_{MMS} = \sum_i \sum_j (Faecal_{ij,MMS} + Urine_{ij,MMS}) \quad (3B.1a_10c)$$

Where $EF_{(MMS)}$ = emission factor (N_2O -N kg/ N excreted) for the different MMS (Appendix 5.A.9)

C_g = 44/28 factor to convert elemental mass of N_2O to molecular mass

5.4.2.3 Indirect nitrous oxide emissions

Atmospheric Deposition

The mass of dairy waste volatilised (Gg N) from the MMS is calculated as:

$$MN_{ATMOS_i} = \sum_j MMS_j ((FN_{ij,MMS} + UN_{ij,MMS}) \times FracGASM_{MMS}). \quad (3B.5a_1)$$

Where $FracGASM_{MMS}$ = the fraction of N volatilised for dairy MMS (Appendix 5.A.9)

Atmospheric deposition emissions from dairy MMS are calculated as:

$$E = \sum_i (MN_{ATMOS_i} \times EF \times C_g). \quad (3B.5a_2)$$

Where E = annual emissions from atmospheric deposition (Gg N_2O)

EF = 0.0039 (Gg N_2O -N/Gg N) (Inorganic Fertiliser EF for irrigated pasture - Table 5.23)

C_g = 44/28 factor to convert elemental mass of N_2O to molecular mass

Leaching and Runoff

Emissions associated with leaching and runoff are only estimated for the solid storage MMS. Leaching and runoff from dairy effluent ponds is considered negligible and leaching and runoff from waste deposited on pasture or distributed to pasture through drains or sump dispersal systems is estimated and reported in the agricultural soils section.

A CS N_2O EF for leaching and runoff is used, which is based on a synthesis of the latest internationally-assessed science, as reported in IPCC (2019). The *2019 Refinement to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories* (IPCC 2019) informed improvements to Australia's country-specific emission estimation approaches consistent with decision 24/CP.19 (Annex I.E, para 10, *Revision of the UNFCCC reporting guidelines on annual inventories for Parties included in Annex I to the Convention*).

Consistent with decision 24/CP.19 (Annex I.E, para 10), this country-specific approach draws on IPCC 2019 to the extent it is better able to reflect Australia's situation than IPCC 2006. The introduction of the new estimation approaches has improved the accuracy and completeness of Australia's inventory.

The amount of N available for leaching and runoff (MN_{LEACH}) is calculated as:

$$MN_{LEACH} = \sum_i \sum_j ((FN_{ijMMS=4} + UN_{ijMMS=4}) \times \text{FracWET}_{MMSi} \times \text{FracLEACH}_{MS}) \quad (3B.5a_3)$$

Where $FN_{ijMMS=4}$ and $UN_{ijMMS=4}$ = mass of N in solid storage
 FracWET_{MMSi} = fraction of N available for leaching and runoff (Appendix 5.J.2)
 FracLEACH_{MS} = 0.02 (Gg N/Gg applied) (CS EF, source IPCC (2019)) fraction of N lost through leaching and runoff

Annual leaching and runoff emissions from dairy MMS are calculated as:

$$E = MN_{LEACH} \times EF \times C_g \quad (3B.5a_4)$$

Where MN_{LEACH} = mass of N lost through leaching and runoff (Gg N)
 $EF = 0.011$ (Gg N_2O-N /Gg N) (CS EF, source IPCC (2019))
 $C_g = 44/28$ factor to convert elemental mass of N_2O to molecular mass

5.4.3 Beef cattle – pasture (3.B.1.B)

5.4.3.1 Methane

Methane production from the manure (M_{ijkl} kg/head/day) of pasture-based beef cattle is calculated as:

$$M_{ijkl} = I_{jktn} \times (1 - \text{DMD}_{ijk}) \times ((PW_j \times \text{EFW}) + (PT_j \times \text{EFT})) \quad (3B.1b_1)$$

Where I_{jktn} = dry matter intake calculated in Section 5.3.2.2
 DMD_{ijk} = dry matter digestibility (expressed as a fraction) (Appendix 5.B.3)
 EFW = warm emission factor (kg CH_4 / kg DM Manure), calculated in Section 5.4.1.1
 EFT = temperate emission factor (kg CH_4 / kg DM Manure), calculated in Section 5.4.1.1
 PW_j = proportion of animals in warm climate region (Appendix 5.B.7)
 PT_j = proportion of animals in temperate climate region (Appendix 5.B.7)

The annual methane production (Gg) from the manure of pasture-based beef cattle is calculated as:

$$\text{Total} = \sum_i \sum_j \sum_k \sum_l (N_{ijkl} \times M_{ijkl} \times 91.25) \times 10^{-6} \quad (3B.1b_2)$$

Where N_{ijkl} = numbers of beef cattle in each State, class and season
 M_{ijkl} = methane production (kg/head/day)

5.4.3.2 Nitrous oxide emissions

As the manure of pasture-based beef cattle is deposited direct to pasture range and paddock (PRP), there are no direct or indirect manure management N_2O emissions. The nitrogen voided in dung and urine of grazing livestock, as calculated in this section, provides the basis for calculating nitrous oxide emissions from agricultural soils in source category 3D.

The amount of nitrogen retained by the body (NR_{ijkln} kg/head/day) is calculated as the amount of nitrogen retained as milk and body tissue such that:

$$NR_{ijkln} = (0.032 \times MP_{ijkln} / 6.38) + \{ \{ (0.212 - 0.008(L_{ijkln} - 2)) - [(0.140 - 0.008(L_{ijkln} - 2)) / (1 + \exp(-6(Z_{ijkln} - 0.4)))] \} \times (LWG_{ijkln} \times 0.92) \} / 6.25 \quad (3B.1b_3)$$

Where MP_{ijkln} = milk production (kg/head/day) calculated as: proportion of cows lactating (LC_{ijkl}) \times milk production
 In areas where Brahman cross breeds are dominant (NT, Qld and Kimberly WA) milk production is 4 kg/day for cows >2 years old in the first season after calving and 3 kg/day in the second season. In other areas where Hereford or Shorthorn breeds are dominant (all other States) milk production is considered to be 6 and 4 kg/day respectively (Appendix 5.B.5)

L_{ijkln} = Intake relative to that needed for maintenance. Calculated as actual intake divided by maintenance intake (i.e. intake of non-lactating animal with LWG set to zero calculated by equation 3A.1b_1)

Z_{ijkln} = relative size - (liveweight / standard reference weight (Appendix 5.B.1 and 5.B.6))

LWG_{ijkln} = liveweight gain (kg/day) (Appendix 5.B.2)

Nitrogen excreted in faeces (F_{ijkln} kg/head/day) is calculated, using equations developed by the SCA (1990) and Freer *et al.* (1997), as the indigestible fraction of the undegraded protein from solid feed, microbial crude protein and milk protein plus the endogenous faecal protein, such that:

$$F_{ijkln} = \{ \{ 0.3((I_{ijkln} \times CP_{ijkl}) \times (1 - [(DMD_{ijkl} + 10) / 100])) + 0.105(ME_{ijkl} \times I_{ijkln} \times 0.008) + (0.0152 \times I_{ijkln}) \} / 6.25 \} + (0.08(0.032 \times MC_{ijkl}) / 6.38) \quad (3B.1b_4)$$

Where I_{ijkln} = dry matter intake (kg/head/day) as calculated in Section 5.3.2.2

CP_{ijkl} = crude protein content of feed dry matter expressed as a fraction (Appendix 5.B.4)

DMD_{ijkl} = dry matter digestibility (expressed as a per cent) (Appendix 5.B.3)

ME_{ijkl} = metabolizable energy (MJ/kg DM) calculated by Minson and McDonald (1987) as:

$ME = 0.1604 DMD_{ijkl} - 1.037$; (DMD expressed as per cent)

MC_{ijkl} = milk intake (kg/head/day). In areas where Brahman cross breeds are dominant (NT, Qld and Kimberly WA) milk intake is 4 kg/day for animals in the first season after birth and 3 kg/day in the second season

In other areas where Hereford or Shorthorn breeds are dominant (all other States) intake is 6 and 4 kg/day (Appendix 5.B.5)

Nitrogen excreted in urine (U_{ijkln} kg/head/day) is calculated by subtracting NR_{ijkl} , F_{ijkl} and dermal protein loss from the nitrogen intake such that:

$$U_{ijkln} = (I_{ijkln} \times CP_{ijkl} / 6.25) + (0.032 \times MC_{ijkl} / 6.38) - NR_{ijkl} - F_{ijkl} - [(1.1 \times 10^{-4} \times W_{ijkl}^{0.75}) / 6.25] \quad (3B.1b_5)$$

Where W_{ijkl} = liveweight (kg) (Appendix 5.B.1)

The total annual faecal ($AF_{ijkln \text{ MMS}=14}$ Gg) and urinary ($AU_{ijkln \text{ MMS}=14}$ Gg) nitrogen excreted to PRP is calculated as:

$$AF_{ijkln \text{ MMS}=14} = (N_{ijkln} \times F_{ijkln} \times 91.25) \times 10^{-6} \quad (3B.1b_6a)$$

$$AU_{ijkln \text{ MMS}=14} = (N_{ijkln} \times U_{ijkln} \times 91.25) \times 10^{-6} \quad (3B.1b \ 6b)$$

Where N_{ijkln} = the number of beef cattle adjusted for feedlot cattle in each State, region, season and class

5.4.4 Beef cattle – feedlot (3.B.1.C)

5.4.4.1 Methane

The high density of animals in feedlots results in high concentrations of manure from which methane can be produced when the dung pack becomes moistened and anaerobic microsites occur. Emissions may also arise from compacted manure stockpiles which are typically anaerobic, and from effluent storage ponds built to contain runoff. These storage ponds are usually anaerobic, providing conditions conducive to methane production.

However, as most manure is handled in drylot and solid storage, only a small fraction of the potential methane emissions are generated.

Volatile solid production for beef cattle in feedlots (VS_j kg/head/day) was estimated using a calculation from the mass balance model developed for Australian feedlots – BeefBal (McGahan *et al.* 2004) and the intakes developed to calculate enteric methane production:

$$VS_j = I_j \times (1 - DMD_j \times (1 - A)) \quad (3B.1c_1)$$

Where I_j = dry matter intake as calculated in section 5.3.2.3
 DMD_j = DM digestibility expressed as a fraction (Appendix 5.C.2)
 A = ash content expressed as a fraction (16 per cent) – The ash content fraction is used in BeefBal, and is based on measured data from Australia. Data presented in Gopalan *et al.* (2013) confirmed VS fractions in fresh manure of between 79 per cent and 88 per cent with an average of 83 per cent. These results support the use of an ash content of manure of 16 per cent

Methane production from the manure management (M_j kg/head/day) is then calculated as:

$$M_j = VS_j \times B_o \times iMCF_i \times \rho \quad (3B.1c_2)$$

Where B_o = emissions potential (0.19m³ CH₄/kg VS (IPCC 2019))
Australia's B_o value is based on independent research measuring average B_o values in Australian feedlots. Results obtained were very similar to the IPCC values for North America, and therefore, it was recommended that the North American B_o value be applied to Australia (Wiedemann *et al.* 2014). These findings constitute an independent validation of the use of the default value for North America as a CS value.
 $iMCF_i$ = integrated MCF for feedlot cattle in each state (Appendix 5.C.3)
 ρ = density of methane (0.6784 kg/m³) – Taken from the *National Greenhouse and Energy Reporting (Measurement) Determination 2008*

Annual methane production (Gg) from the manure of beef cattle in feedlots is calculated as:

$$E = \sum_j (365 \times N_{ij} \times M_j \times 10^{-6}) \quad (3B.1c_3)$$

Where N_{ij} = Annual equivalent numbers of beef cattle in feedlots
 M_j = methane production (kg/head/day)

5.4.4.2 Direct nitrous oxide emissions

The excretion of nitrogen from feedlot cattle is estimated from nitrogen intake (NI_j) and the fraction retained (NR_j).

Nitrogen intake NI_j (kg/head/day) of feedlot cattle is calculated by:

$$NI_j = I_j \times CP_j / 6.25 \quad (3B.1c_4)$$

Where I_j = dry matter intake, calculated in section 5.3.2.3
 CP_j = crude protein content of feed expressed as a fraction (Appendix 5.C.2)
 6.25 = factor for converting crude protein into nitrogen

Nitrogen excretion NE_j (kg/head/day) is calculated by:

$$NE_j = NI_j \times (1 - NR_j) \quad (3B.1c_5)$$

Where NR_j = nitrogen retention expressed as a fraction of intake (Appendix 5.C.1)

Annual nitrogen excretion (AE_{ij} Gg/year) from feedlot cattle is calculated as:

$$AE_{ij} = N_{ij} \times NE_j \times 365 \times 10^{-6} \quad (3B.1c_6)$$

Where N_{ij} = Annual equivalent numbers of beef cattle in each class in each State

Total direct emissions of nitrous oxide from feedlot cattle (Gg) can be calculated as follows:

$$TotalMMS = \sum_i \sum_j (AE_{ij} \times iNOF \times C_g) \quad (3B.1c_7)$$

Where $iNOF$ = integrated N_2O emission factor for each feedlot class and state (Appendix 5.C.3)
 C_g = 44/28 factor to convert elemental mass of N_2O to molecular mass

5.4.4.3 Indirect nitrous oxide emissions (3.B.5)

Atmospheric Deposition

Integrated $FracGASM_{MMS}$ values (Appendix 5.C.3) based on the IPCC (2006) default and Australian research (Appendix 5.C.7) are used to estimate N volatilisation.

The mass of feedlot waste volatilised (Gg) is calculated as:

$$MN_{ATMOS_{ij}} = \sum_i \sum_j (N_{ij} \times AE_{ij} \times iFracGASM_{MMS}) \quad (3B.5c_1)$$

Where AE_{ij} = mass of nitrogen excreted, calculated in Equation 3B.1c_6.
 $iFracGASM_{MMS}$ = integrated fraction of N volatilised from feedlot cattle (Appendix 5.C.3)

Annual atmospheric deposition emissions (Gg N_2O) from MMS are calculated as:

$$E = MN_{ATMOS} \times EF \times C_g \quad (3B.5c_2)$$

Where MN_{ATMOS} = mass of N volatilised (Gg N)
 EF = 0.002 (Gg N_2O -N/Gg N) (Inorganic fertiliser EF for non-irrigated cropping – Table 5.23)
 C_g = 44/28 factor to convert elemental mass of N_2O to molecular mass

Leaching and Runoff

Australian feedlots are managed with strict environmental controls on leaching, requiring the use of an impermeable barrier depending on underlying strata (MLA 2012, Skerman 2000). Leaching is therefore assumed to be zero, while runoff from feedlots is captured in effluent ponds. Emissions associated with waste runoff are therefore included in the direct emission estimates.

5.4.5 Sheep (3.B.2)

5.4.5.1 Methane

Methane production from manure (M_{ijk} kg/head/day) of sheep is calculated as:

$$M_{ijk} = I_{ijk} \times (1 - \text{DMD}_{ijk}) \times \text{EFT} \quad (3B.2_1)$$

Where I_{ijk} = dry matter intake calculated in Section 5.3.3
 DMD_{ijk} = digestibility expressed as a percentage (Appendix 5.D.2)
 EFT = temperate emission factor (kg CH_4 / kg DM Manure)

The annual methane production (Gg) from sheep manure is calculated as:

$$\text{Total} = \sum_i \sum_j \sum_k (N_{ijk} \times M_{ijk} \times 91.25) \times 10^{-6} \quad (3B.2_2)$$

Where N_{ijk} = numbers of sheep in each State, class and season
 M_{ijk} = methane production (kg/head/day)

5.4.5.2 Nitrous oxide emissions

As sheep manure is deposited direct to PRP, there are no direct or indirect manure management N_2O emissions. The nitrogen voided in dung and urine of grazing livestock, as calculated in this section, provides the basis of calculating nitrous oxide emissions from agricultural soils in source category 3D.

The methodology for calculating excretion of nitrogen from sheep makes use of the following algorithms to calculate crude protein input (CPI_{ijk}) and N retention (NR_{ijk}) and from these, the output of nitrogen in faeces and urine.

Crude protein intake CPI_{ijk} (kg/head/day) of sheep is calculated as:

$$\text{CPI}_{ijk} = I_{ijk} \times \text{CP}_{ijk} + (0.045 \times \text{MC}_{ijk}) \quad (3B.2_3)$$

Where I_{ijk} = feed intake (kg DM/head/day) as calculated in Section 5.3.3
 CP_{ijk} = crude protein content of feed intake expressed as a fraction (Appendix 5.D.4)
 MC_{ijk} = milk intake (kg/head/day) calculated as: proportion of lambs receiving milk in each season x milk intake (Appendix 5.D.6). Milk intake assumed to be 1.6 kg/day for the first three months after the birth of lambs

The amount of nitrogen retained by the body (NR_{ijk} kg/head/day) is calculated as the nitrogen retained in milk, wool and body tissue such that:

$$NR_{ijk} = \{(0.045 \times MP_{ijk}) + (WP_{ijk} \times 0.84) + \{[(212-4\{[(EBG_{ijk} \times 1000)/(4 \times SRW_{ijk}^{0.75})] - 1\}) - (140 - 4\{[(EBG_{ijk} \times 1000)/(4 \times SRW_{ijk}^{0.75})] - 1\}) / \{1+\exp(-6(Z_{ijk}-0.4))\}] \times EBG_{ijk}\} / 1000\} / 6.25 \quad (3B.2_4)$$

Where MP_{ijk} = milk production (kg/day) calculated as: proportion of ewes lactating (LE_{ijk}) x milk production
Milk production is considered to be 1.6 kg/day for breeding ewes in the first three months after the birth of lambs
 WP_{ijk} = clean wool production (kg/day) based on ABS average greasy wool production per head multiplied by State average clean yield percentage. Wool production may be reduced by 50 per cent for lactating ewes (SCA 1990). Accordingly, wool production of ewes was apportioned pro rata to give recorded annual average wool production. It is assumed that clean wool consists of 16 per cent water and 84 per cent protein.
 EBG_{ijk} = empty body gain, equivalent to $LWG_{ijk} \times 0.92$
 SRW_{ijk} = standard reference weight (SCA 1990) in Appendix 5.D.7
 Z_{ijk} = relative size (liveweight / standard reference weight) (Appendix 5.D.1 and 5.D.7)

Nitrogen excreted in faeces (F_{ijk} kg/head/day) is calculated using functions developed by SCA (1990) and Freer *et al.* (1997), as the indigestible fraction of the un-degraded protein from solid feed, the microbial crude protein and milk protein plus the endogenous faecal protein, such that:

$$F_{ijk} = \{0.3(CPI_{ijk} \times (1 - [(DMD_{ijk} + 10)/100])) + 0.105(ME_{ijk} \times I_{ijk} \times 0.008) + 0.08(0.045 \times MC_{ijk}) + 0.0152 \times I_{ijk}\} / 6.25 \quad (3B.2_5)$$

Where DMD_{ijk} = digestibility expressed as a percentage (Appendix 5.D.2)
 ME_{ijk} = metabolizable energy (MJ/kg DM) calculated as $0.1604 DMD_{ijk} - 1.037$ (Minson and McDonald 1987)
 MC_{ijk} = milk intake (kg/day) calculated as: proportion of lambs receiving milk in each season x milk intake (Appendix 5.D.6). Milk intake assumed to be 1.6 kg/day for the first three months after the birth of lambs
1/6.25 = factor for converting crude protein into nitrogen

Nitrogen excreted in urine (U_{ijk} kg/head/day) is calculated by subtracting the nitrogen retained (NR_{ijk}) and the nitrogen excreted in faeces (F_{ijk}) from the nitrogen intake such that:

$$U_{ijk} = (CPI_{ijk} / 6.25) - NR_{ijk} - F_{ijk} \quad (3B.2_6)$$

The annual faecal (AF_{ijk} Gg) and urinary (AU_{ijk} Gg) nitrogen excreted to PRP is calculated as:

$$AF_{ijk \text{ MMS}=14} = (N_{ijk} \times F_{ijk} \times 91.25) \times 10^{-6} \quad (3B.2_7a)$$

$$AU_{ijk \text{ MMS}=14} = (N_{ijk} \times U_{ijk} \times 91.25) \times 10^{-6} \quad (3B.2_7b)$$

Where N_{ijk} = the number of sheep in each State, season and class

5.4.6 Swine (3.B.3)

5.4.6.1 Methane

In Australia, swine are generally housed and the liquid waste slurry produced during cleaning is often channelled into lagoons. These lagoons tend to create anaerobic conditions, resulting in a high proportion of the volatile solids being fermented with the formation of methane.

A significant proportion of feed given to swine can be wasted (ranging from 5–20 per cent). This waste feed also contributes volatile solids to the MMS and will result in methane emissions. For completeness, emissions are estimated from all waste entering the MMS.

PIGBAL (Skerman *et al.* 2013) is a nutrient balance model for intensive piggeries in Australia. By entering typical animal characteristics, feed intakes, diet compositions and wastage rates, the model calculates the volatile solids (VS_{ij} kg/head/day) in the animal manure (including urine) and waste feed (Appendix 5.E).

Using this information, CH_4 production from wastes (M_{ij} kg/head/day) can be calculated as:

$$M_{ij} = VS_{ij} \times B_o \times iMCF_i \times \rho \quad (3B.3_1)$$

Where VS_{ij} = volatile solids production (kg/head/day) (Appendix 5.E.3)
 B_o = methane emission potential ($0.45m^3 CH_4/kg VS$ – IPCC 2019)
 $iMCF_j$ = integrated methane conversion factor based on the proportion of different manure management regimes (Appendix 5.E.4)
 ρ = density of methane ($0.6784kg/m^3$) – From the *National Greenhouse and Energy Reporting (Measurement) Determination 2008*

The annual methane production (Gg) from the wastes of Australian swine is calculated as:

$$E = \sum_i \sum_j (365 \times N_{ij} \times M_{ij} \times 10^{-6}) \quad (3B.3_2)$$

Where N_{ij} = numbers of swine in each class for each State
 M_{ij} = methane production (kg/head/day)

5.4.6.2 Direct nitrous oxide emissions

Swine are fed high quality diets with high levels of crude protein. The rapid growth rates of most swine results in a relatively high proportion of this nitrogen being retained in the body. Swine may excrete between 45 and 65 per cent of nitrogen consumed in feed (King and Brown 1993, King *et al.* 1993).

Wasted feed also contributes nitrogen to the MMS and is included in the estimation of emissions for completeness. The nutrient balance model PIGBAL (Skerman *et al.* 2013) is used to estimate total nitrogen in wastes based on typical animal characteristics, feed intakes, feed types and wastage rates (Appendix 5.E).

Allocations to the different MMS have changed over time (Table 5.E.5), with an increase in swine being housed on deep litter resulting in a decrease of allocations to effluent ponds (Wiedemann *et al.* 2014). Intensification of the industry has also occurred, with typical animal mass increasing across every State throughout the timeseries, while N excretion rates have decreased. This has resulted in a continual increase to the N_2O IEF, from 0.0245 kg N_2O / head/year in 1990 to 0.0787 in 2018.

Annual nitrogen (AE_{ij} Gg/year) from swine manure and waste feed is calculated as:

$$AE_{ij} = N_{ij} \times E_{ij} \times 10^{-6} \quad (3B.3_3)$$

Where N_{ij} = numbers of swine in each class in each State

E_{ij} = nitrogen in waste (kg/head/year) as calculated by PIGBAL (Appendix 5.E.3)

Total emissions of nitrous oxide from the different MMS (Gg) can then be calculated as follows:

$$Total_{MMS} = \sum_i \sum_j (AE_{ij} \times iNOF \times C_g) \quad (3B.3_4)$$

Where $iNOF$ = the integrated nitrous oxide emission factor for swine in each state (Appendix 5.E.4)

C_g = 44/28 factor to convert elemental mass of N_2O to molecular mass

5.4.6.3 Indirect nitrous oxide emissions

Atmospheric deposition

Australia has developed integrated $FracGASM_{MMS}$ values (Appendix 5.E.4) for swine based on default IPCC (2006) and CS values (Appendix 5.E.8).

The mass of piggery waste volatilised is calculated as:

$$MATMOS = \sum_i \sum_k (N_{ij} \times AE_{ij} \times iFracGASM_{MMS}) \quad (3B.5c_1)$$

Where AE_{ij} = mass of nitrogen excreted, calculated in Equation 3B.3_3

$iFracGASM_{MMS}$ = the integrated fraction of N volatilised for the swine industry (Appendix 5.E.4)

Annual indirect nitrous oxide production (Gg N_2O) from swine MMS is calculated as:

$$E = MNATMOS \times EF_{ij} \times C_g \quad (3B.5c_2)$$

Where $MNATMOS$ = mass of N volatilised (Gg N)

EF_{ij} = 0.002 (Gg N_2O -N/Gg N) (Inorganic Fertiliser EF for non-irrigated cropping – Table 5.23)

C = 44/28 factor to convert elemental mass of N_2O to molecular mass

Leaching and runoff

Leaching and runoff from piggery facilities (with the exception of outdoor piggeries) is considered negligible because of strict environmental regulations in all States of Australia. The emissions associated with leaching and runoff are therefore only estimated for the drylot MMS.

$$MNLEACH_{ij} = \sum_i \sum_k (N_{ij} \times AE_{ij} \times MSi_{MMS=S} \times FracWET_{MMSi} \times FracLEACH_{MS}) \quad (3B.5c_3)$$

Where $MNLEACH_{ij}$ = mass of N lost through leaching and runoff (Gg N)

AE_{ij} = mass of nitrogen in waste, calculated in equation 3B.3_3

$MSi_{MMS=S}$ = fraction of waste handled through drylot (Appendix 5.E.5)

$FracWET_{MMSi}$ = fraction of N available for leaching and runoff (Appendix 5.J.2)

$FracLEACH_{MS}$ = 0.02 (Gg N/Gg applied) (CS EF, source IPCC (2019)) fraction of N lost through leaching and runoff

Annual leaching and runoff emissions (Gg N₂O) from swine MMS are calculated as:

$$E = MN_{LEACH_{ij}} \times EF \times C_g \quad (3B.5c_4)$$

Where EF = 0.011 (Gg N₂O-N/Gg N) (CS EF, IPCC (2019))

C_g = 44/28 factor to convert elemental mass of N₂O to molecular mass

5.4.7 Poultry (3.B.4.G)

Table 5.16 Symbols used in algorithms for poultry

State (i)	Poultry classes (j)	Poultry subclass
1 = ACT	1 = Layer	
2 = Northern Territory	2 = Meat	2a = Meat chicken growers
3 = NSW		2b = Meat chicken breeders
4 = Queensland		2c = Other
5 = Tasmania		
6 = South Australia		
7 = Victoria		
8 = Western Australia		

5.4.7.1 Methane

The majority of Australia's poultry population are housed indoors which promotes conditions for the concentration and concentrated treatment of faecal wastes. Methane from manure is formed from the organic fraction of the manure (volatile solids).

Volatile solid production (VS_{ij} kg/head/day) for poultry was estimated using information on feed intakes and dry matter digestibility:

$$VS_{ij} = I_{ij} (1 - DMD_{ij}) \times (1 - A) \quad (3B.4g_1)$$

Where I_{ij} = dry matter intake (Appendix 5.F.1)

DMD_{ij} = digestibility expressed as a fraction (Appendix 5.F.1)

A = ash content of manure expressed as a fraction (Appendix 5.F.1)

Methane production from poultry manure (M_{ij} kg/head/day) can then be calculated as:

$$M_{ij} = VS_{ij} \times B_o \times iMCF_{ij} \times \rho \quad (3B.4g_2)$$

Where B_o = emission potential (0.36 m³ CH₄/kg VS for meat and 0.39 m³ CH₄ / kg VS for layers (IPCC 2019))

iMCF_{ij} = Integrated methane conversion factor (Appendix 5.F.2)

ρ = density of methane (0.6784 kg/m³) - From the *National Greenhouse and Energy Reporting (Measurement) Determination 2008*

Annual methane production (Gg) for poultry is calculated as:

$$E = \sum_i \sum_j (365 \times N_{ij} \times M_{ij} \times 10^{-6}) \quad (3B.4g_3)$$

Where N_{ij} = number of birds in each class and State

M_{ij} = methane production (kg/head/day)

5.4.7.2 Direct nitrous oxide emissions

The methodology for calculating excretion of nitrogen from meat chickens and layers makes use of the following algorithms to calculate nitrogen intake (NI_{ij}) and retention (NR_{ij}) and from these, the output of nitrogen in manure.

The nitrogen intake NI_j (kg/head/day) of poultry is calculated by:

$$NI_j = I_j \times CP_j / 6.25 \quad (3B.4g_4)$$

Where I_j = dry matter intake in kg/day (Appendix 5.F.1)
 CP_j = dietary crude protein expressed as a fraction (Appendix 5.F.1)
 6.25 = factor for converting crude protein into nitrogen

Nitrogen excretion (NE_{ij}) (Gg/head/year) is calculated by:

$$NE_{ij} = NI_j (1 - NR_j) \times 365 \times 10^{-6} \quad (3B.4g_5)$$

Where NR_j = nitrogen retention as a proportion of intake (Appendix 5.F.1)

Total emissions of nitrous oxide from the different MMS (Gg) can then be calculated as follows:

$$TotalMMS = \sum_i \sum_j (N_{ij} \times NE_{ij} \times iNOF_j \times C_g) \quad (3B.4g_6)$$

Where N_{ij} = annual equivalent number of birds in each class and state
 NE_{ij} = N excretion (Gg/head/year)
 $iNOF_j$ = the integrated nitrous oxide emission factor (Appendix 5.F.2)
 C_g = 44/28 factor to convert elemental mass of N_2O to molecular mass

5.4.7.3 Indirect nitrous oxide emissions (3.B.5)

Atmospheric deposition

Integrated FracGASM values (Appendix 5.F.2) based on default IPCC (2006) and CS values (Appendix 5.F.7) are used to estimate N volatilisation from poultry.

Mass of poultry waste volatilised (Gg N) is calculated as:

$$MATMOS = \sum_i \sum_j (N_{ij} \times NE_{ij} \times iFracGASMMS_j) \quad (3B.5d_1)$$

Where NE_{ij} = mass of nitrogen excreted (Gg/head/year), calculated in Equation 3B.4g_5
 $iFracGASMMS_j$ = the integrated fraction of N volatilised for the meat and layer industries (Appendix 5.F.2)

Annual atmospheric deposition emissions (Gg N_2O) from poultry MMS are calculated as:

$$E = MNATMOS \times EF_{ij} \times C_g \quad (3B.5d_2)$$

Where EF_{ij} = 0.0021 (Gg N_2O -N/Gg N) (Meat = inorganic fertiliser EF for non-irrigated pastures)
 EF_{ij} = 0.002 (Gg N_2O -N/Gg N) (Layers = inorganic fertiliser EF for non-irrigated cropping – Table 5.23)
 C_g = 44/28 factor to convert elemental mass of N_2O to molecular mass

Leaching and runoff

Leaching and runoff from poultry facilities (with the exception of free range operations and manure stockpiles) is considered negligible. Therefore the emissions associated with waste leaching and runoff are only estimated for manure stockpiles. Emissions from free range operations are estimated in the agricultural soils category 3D.

$$MN_{LEACH} = \sum_i \sum_j (N_{ij} \times NE_{ij} \times MSi_{MMS=4-5} \times \text{FracWET}_{MMSi} \times \text{FracLEACH}_{MS}) \quad (3B.5d_3)$$

Where $MN_{LEACH_{ij}}$ = mass of N lost through leaching and runoff (Gg N)
 NE_{ij} = mass of nitrogen excreted (Gg/head/year), calculated in Equation 3B.4g_5
 $MSi_{MMS=4-5}$ = fraction of waste handled through drylot and solid storage (Appendix 5.F.3)
 FracWET_{MMSi} = Fraction of N available for leaching and runoff (Appendix 5.J.2)
 FracLEACH_{MS} = 0.02 (Gg N/Gg applied) (CS EF, source IPCC (2019)) fraction of N lost through leaching and runoff

Annual leaching and runoff emissions (Gg N_2O) from poultry MMS are calculated as:

$$E = \sum_i \sum_j (MN_{LEACH_{ij}} \times EF \times C_g) \quad (3B.5d_4)$$

Where EF = 0.011 (Gg N_2O -N/Gg N) (CS EF, source IPCC (2019))
 C_g = 44/28 factor to convert elemental mass of N_2O to molecular mass

5.4.8 Other livestock (including 3.B.4.A-F, H and I)

5.4.8.1 Methane

Goats, deer, buffalo, camels, alpaca, horses, mules and asses, emus and ostriches are range-kept livestock and hence, manure deposition typically occurs in a dispersed fashion. Little is known about the amount of manure produced by the livestock types in this group. In the absence of adequate information, it is assumed that the rates of manure production (DMM_{ij} kg DM/head/year) can be scaled to those calculated for either sheep or beef cattle, based on the comparative size of the animals (Appendix 5.G.1). For example, the IPCC default weight for horses (377 kg) and buffalo (380 kg) are consistent with the average weight of beef cattle (380 kg), while the default weight of mules/asses (130 kg) and goats (38.5 kg) are consistent with one third of beef cattle (127 kg) and sheep (45 kg) weights respectively.

Methane production from the manure of other livestock (M_{ij} kg/head/day) is calculated as:

$$M_{ij} = (DMM_{ij} \times PW_i \times EFW) + (DMM_{ij} \times PT_i \times EFT) \quad (3B.4_1)$$

Where DMM_{ij} = dry matter in manure (Appendix 5.G.1)
 EFW = warm emission factor (kg CH_4 / kg DM Manure), calculated in Section 5.4.1.1
 EFT = temperate emission factor (kg CH_4 / kg DM Manure), calculated in Section 5.4.1.1
 PW_i = proportion of animals in warm climate region (Appendix 5.G.3)
 PT_i = proportion of animals in temperate climate region (Appendix 5.G.3)

Annual methane production (Gg) from manure of other livestock is calculated as:

$$\text{Total} = \sum_i \sum_j (N_{ij} \times M_{ij}) \times 10^{-6} \quad (3B.4_2)$$

Where N_{ij} = numbers of animals in each State
 M_{ij} = methane production (kg/head/day)

5.4.8.2 Nitrous oxide emissions

As the manure of other livestock is deposited direct to PRP, there are no direct or indirect manure management N₂O emissions. The nitrogen voided in dung and urine of grazing livestock, as calculated in this section, provides the basis of calculating nitrous oxide emissions from agricultural soils in source category 3D.

In the absence of adequate species specific information, it is assumed that the rates of nitrogen excretion (E_{ij} kg/head/year) can be scaled to those calculated for either sheep or beef cattle, based on the comparative size of the animals (Appendix 5.G.2).

The annual nitrogen (AE_{ij} Gg/year) excreted to PRP is calculated as:

$$AE_{ij\text{MMS}=14} = (N_{ij} \times E_{ij}) \times 10^{-6} \quad (3B.4_3)$$

Where N_{ij} = numbers in each State

E_{ij} = nitrogen excreted (kg/head/year) (Appendix 5.G.2)

The annual nitrogen excreted in faeces (AF_{ij}) and Urine (AU_{ij}) to PRP is calculated as:

$$AF_{ij\text{MMS}=14} = \sum_j (AE_{ij\text{MMS}=14} \times PMF) \quad (3B.4_4)$$

$$AU_{ij\text{MMS}=14} = \sum_j (AE_{ij\text{MMS}=14} \times PMU) \quad (3B.4_5)$$

Where PMF = the proportion of waste that is faeces. Assumed to be 0.29 (based on average of cattle and sheep)

PMU = the proportion of waste that is urine. Assumed to be 0.71 (based on average of cattle and sheep)

5.4.9 Uncertainties and time series consistency

A quantitative assessment of uncertainty was undertaken and uncertainties for manure management were estimated to be in the order of 37–55 per cent. Further details are provided in Annex 2.

Time series consistency is ensured by the use of consistent methods and full recalculations in the event of any refinement to methodology. See Section 5.2.1 regarding how changes to data collection methods by the Australian Bureau of Statistics have been addressed to ensure time series consistency of livestock numbers, and reasons for differences in beef cattle and poultry populations with published FAO data..

5.4.10 Source specific QA/QC

5.4.10.1 Activity data

The Australian Bureau of Statistics (ABS) is the national statistical agency of Australia and is the key provider of activity data for this source category. ABS has in place a range of quality assurance-quality control procedures associated with survey design, data input and consistency checks on the survey results and the aggregated values.

Data quality in the inventory is also kept under review by the Department.

This source category is also covered by the general QA/QC procedures detailed in Chapter 1. The QC procedure “ensuring consistency in data between categories” is of specific importance for this category. The AGEIS ensures that activity and livestock characterisation data used across multiple categories is entered only once and that intakes or emissions calculated in one category form the input for other categories.

5.4.10.2 Implied EFs

Comparison with IPCC values

As CS tier 2 methods are used to estimate emissions from cattle, sheep, pigs and poultry, the IEFs have been compared with IPCC defaults (Table 5.17).

Table 5.17 Implied EFs – Methane manure management (kg/head/year)

Livestock type	Australia	IPCC default (Oceania)
Dairy cattle	15	23–31
Beef cattle		
Pasture	4.86	1–2
Feedlot	3.5	1–2
Sheep	0.34	0.19–0.37
Swine	23.19	11–24
Poultry	0.04	0.02–1.4

Source: IPCC (2006).

Dairy cattle

The IEFs for dairy cattle differ from the IPCC defaults due to the allocation of waste to different MMS. Australia assumes that 80–88 per cent of waste is voided at pasture compared with 76 per cent in the IPCC (2006) default.

Pasture beef cattle

The IEF for range-kept beef cattle is higher than the IPCC default EF range. Reasons for this difference include:

- Australia assumes that 5 per cent of pasture beef cattle manure is deposited into constructed ponds, which is included in manure management CH₄ emissions. The anaerobic lagoon EF applied to constructed ponds is significantly higher than the PRP EF, therefore, raising Australia's overall IEF.
- The default factors for Oceania include a number of developing nations in the region, which have different production systems for livestock compared to those in Australia.

Comparison with Annex-1 IEFs

Australia's approach to the estimation of emissions from manure deposited by cattle places Australia's IEF within the range of Annex-1 IEFs (Figure 5.4). The Australian value falls within the 4–6 IEF group.

Figure 5.4 Cattle manure management IEF comparisons (kg CH₄/head/year)

Australia's manure management CH₄ IEF for cattle is also comparable to Annex 1 parties with similar livestock production systems, such as New Zealand (ranging from 2.2 to 5.2 kg CH₄/head/year).

Feedlot cattle

The IPCC default B0 value for North America has been chosen for feedlot beef cattle based on the recommendations contained in Wiedemann *et al.* (2014). They noted that the IPCC (2006) default for Oceania did not correspond with measurements by Gopalan *et al.* (2013) from four Australian feedlots, which were more aligned to the IPCC default for North America.

Sheep

Australia's sheep IEF is within the IPCC default EF range.

The reasons for being at the higher end of the range are:

- Australia assumes that 5 per cent of sheep manure is deposited into constructed ponds, which is included in manure management CH₄ emissions. The anaerobic lagoon EF applied to constructed ponds is significantly higher than the PRP EF, therefore, raising Australia's overall IEF.
- The default factors for Oceania include a number of developing nations in the region which have different production systems for livestock compared to those in Australia.

Swine

The swine IEF is on the high end of the IPCC range. The IPCC (2006) default assumes that 50 per cent of manure passes through an anaerobic pond, while Australian management practices for swine see this elevated to around 70 per cent.

Poultry

The poultry IEF is within the range of the IPCC (2006) default EFs.

5.4.10.3 Volatile solids

The major source of methane emissions from manure management are from the intensive livestock industries. As the intake calculation for cattle and the volatile solid calculations for swine and poultry differ from the IPCC tier 2 methodologies, the estimated volatile solids were compared against the IPCC defaults. These were found to be comparable for dairy cattle, swine and poultry (Table 5.18). The volatile solid production of feedlot cattle was lower than the IPCC (2006) defaults, as an ash content of 16 per cent is used compared with the default of 8 per cent. The slightly higher values reported for swine are likely the consequence of including VS from feed waste.

Table 5.18 Volatile solids (kg/head/day)

Livestock type	Australia	IPCC 2006 default	IPCC 2019
Dairy cows	3.3	1.9-5.4	2.9-5.4
Beef cattle - Feedlot	1.7	1.4-3	2.3-3.9
Swine			
Breeders	0.4-0.55	0.3-0.5	0.3-0.6
Other pigs	0.39	0.27-0.3	0.3-0.32
Poultry			
Layers	0.014	0.02	0.02
Meat	0.016-0.017	0.01-0.02	0.01-0.02

Source: IPCC (2006 and 2019).

5.4.10.4 Nitrogen excretion

The CS estimates of nitrogen excretion were compared against the IPCC defaults (Table 5.19). Feedlot cattle, sheep and poultry excretion rates are consistent with IPCC (2019) values.

For other animals, excretion rates differ from the IPCC values. However, the IPCC *Guidelines* do not provide the data on which the default excretion/retention rates are based, so it is impossible to determine whether it is the assumption regarding feed quality causing the difference in excretion rates.

Dairy cattle excretion rates are consistent with the IPCC (2019) values. The CS method was compared with excretion rates generated by the IPCC tier 2 and New Zealand methods, and was found to give comparable results. Excretion rates for mature animals were almost identical, while for rapidly growing animals (< 1 year old), the CS method estimated slightly lower N retention and hence, higher N excretion than the other methods. Excretion rates for pasture fed beef cattle are just outside the range given by the IPCC. Australia would expect to be at the low end of the range of excretion rates due to the quality of pasture available for range-kept cattle consumption.

Swine N excretion rates were generally consistent with IPCC (2019) values, although Australia's 'other pig' rate was slightly higher. Differences could be related to different feed intake, crude protein intake or N retention assumptions compared to the IPCC.

Table 5.19 Nitrogen excretion rates (kg/head/year)

Livestock type	Australia	IPCC 2006	IPCC 2019
Dairy cattle (455 kg)	124	58–80	42–142
Beef cattle			38–94 (other cattle)
Pasture (378 kg)	42	43–69	43–69
Feedlot (524 kg)	71	60–96	60–96
Sheep (43 kg)	7	5–8	5–9
Swine			
Sows (188 kg)	18	21–34	11–27
Growers (39 kg)	11	4–7	7–17
Poultry	0.6–0.7	0.6–1.0	0.4–0.7

Source: IPCC 2006 and 2019.

5.4.10.5 External review

Comprehensive expert peer review of the methodologies, activity data and livestock characterisation data were conducted for sheep in 2000–01; dairy and feedlot cattle, swine and poultry in 2014; and QLD/NT beef cattle on pastures in 2015. The reviews involved agricultural experts from industry, government and academia.

5.4.11 Recalculations since the 2019 Inventory

Recalculations for Manure Management have occurred in the 2022 submission due to:

- The application of the default factor of 0.02 for the parameter FracLEACH-MS (leaching from solid manure storage) from the 2019 Refinement to the 2006 IPCC Guidelines (vol. 4, chap. 10, table 10.22), according to ERT recommendation A.3.

Table 5.20 Manure Management (3.B): recalculation of total CO₂-e emissions: 1990–2019

Year	2021 submission	2022 submission	Change	
	(Gg CO ₂ -e)	(Gg CO ₂ -e)	(Gg CO ₂ -e)	(per cent)
1990	6,389	6,380	-9	-0.1
2000	6,295	6,282	-13	-0.2
2005	6,933	6,916	-17	-0.2
2010	6,370	6,352	-19	-0.3
2011	6,492	6,473	-19	-0.3
2012	6,663	6,643	-20	-0.3
2013	6,664	6,643	-20	-0.3
2014	6,793	6,772	-20	-0.3
2015	6,694	6,673	-20	-0.3
2016	6,536	6,515	-21	-0.3
2017	6,753	6,732	-21	-0.3
2018	6,863	6,842	-20	-0.3
2019	6,433	6,413	-19	-0.3

5.4.12 Source specific planned improvements

The inventory improvement plan for the agriculture sector identified areas which require updating or review over the next few years. Areas for improvement are identified through the UNFCCC expert reviews, domestic QA/QC processes or the expected availability of new data or empirical studies which could improve accuracy of the inventory.

For manure management the following areas have been identified for review and/or change:

1. *Manure mass and N₂O emissions* – Recent Australian research (Redding *et al.*, 2015); directly measured emissions from the manure layers on several feedlot surfaces using a large chamber. A key finding of this research was that there was no significant relationship between manure N-mass and N₂O emission, contrary to the IPCC (2006) approach. This finding was supported by the recent review of the drylot N₂O EF by Wiedemann and Longworth (2020), who noted that as manure nitrogen is not the first limiting factor driving N₂O emissions from drylots, reducing manure N is less likely to influence emissions than would be suggested by the EF. Research to provide a prediction method based on key drivers; temperature, rainfall and manure moisture (Parker *et al.*, 2018, Redding *et al.*, 2015, Sun *et al.*, 2016, Waldrip *et al.*, 2016), may lead to better process knowledge and a revised emission factor or prediction method in the future. (Wiedemann & Longworth 2020)
2. *Methane Capture and Destruction* – a number of piggeries and poultry operations are capturing and destroying methane from digesters/covered lagoons. Those farms who participated in the Emissions Reduction Fund have now reported data to the Clean Energy Regulator. This data will be reviewed to determine if it can be used to develop a more accurate MCF based on measurement data.

5.5 Source Category 3.C Rice Cultivation

5.5.1 Source category description and methodology

Methane is generated during rice growing from the decomposition of plant residues and other organic carbon material in the soil. This generation occurs through microbial action under anaerobic conditions following flooding of the rice crop.

Methane emission rates vary widely, both diurnally in response to immediate environmental factors such as temperature, and also throughout the season in response to crop development and accompanying changes in soil condition. Emission rates are also dependent on more stable factors including soil type and cultivation method (e.g. irrigation regimes, fertiliser application).

All Australian rice is grown under flooded cultivation and production is highly influenced by availability of water for irrigation. Australian rice cultivation does not have large inputs of organic matter as rice stubble is usually burnt and urea fertilisers are used rather than manures.

Most of the rice grown in Australia is concentrated in the Murrumbidgee and Murray valleys of southern New South Wales. Small areas of rice are also grown in north-eastern Victoria. These climates are considered temperate. There has also been very small amounts of rice grown in the warmer areas of northern Queensland and Northern Territory since 2010.

A CS method is applied to estimate emissions from rice cultivation.

The IPCC (2019) EF of 1.19 kg CH₄/ha/day is used, with appropriate scaling factors applied for a continuously flooded water regime (SF_w = 1) and a non-flooded pre-season of > 180 days (SF_p = 0.89). These factors were

selected as they are based on the latest science, are disaggregated by water regime type prior to and during cropping, and they have reduced levels of uncertainty than IPCC (2006) defaults.

Over the average 150 day growing season this gives an emission rate for Australia of 158.9 kg CH₄/ha as per Equation 5.2 in IPCC 2019:

$$\text{Rice EF} = \text{EFc} \times \text{SFw} \times \text{SFp} \times \text{SFo}$$

Where EFc is the baseline EF for continuously flooded fields without organic amendments (1.19 kg CH₄/ha/day)
 SFw is the scaling factor to account for the differences in water regimes during the cultivation period (irrigated, continuously flooded production systems)
 SFp is the scaling factor to account for the differences in water regimes in the pre-season before the cultivation period (non-flooded pre-season > 180 days)
 SFo is the scaling factor for organic amendments (as fertiliser is used rather than manure, this factor is not applied)
 Australia's Rice EF = 1.19 x 150 x 1 x 0.89

Table 5.21 Symbols used in algorithms for rice cultivation

State (i)
1 = ACT
2 = Northern Territory
3 = NSW
4 = Queensland
5 = Tasmania
6 = South Australia
7 = Victoria
8 = Western Australia

Annual production of methane from rice cultivation (E_i Gg) is calculated as:

$$E_i = A_i \times \text{EF} \times 10^{-6} \quad (3C_1)$$

Where A_i = area under rice cultivation (ha)
 EF = emission factor integrated over the whole season (158.9 kg CH₄/ha)

The area under rice cultivation by State for the entire Inventory time series is provided in Appendix 5.L.

5.5.2 Uncertainties and time series consistency

A quantitative assessment of uncertainty was undertaken and uncertainties for rice cultivation were estimated to be in the order of 50 per cent. Further details on the analysis are provided in Annex 2. Time series consistency is ensured by the use of the same methods and data sources for the full time series.

5.5.3 Source specific QA/QC

This source category is covered by the general QA/QC procedures detailed in Chapter 1.

5.5.4 Recalculations since the 2019 Inventory

There were no recalculations affecting this subsector in the 2022 submission.

5.5.5 Source specific planned Improvements

All data and methodologies are kept under review.

5.6 Source Category 3.D Agricultural Soils

5.6.1 Source category description and methodology

Direct and indirect emissions of nitrous oxide from soils arise from microbial and chemical transformations that produce and consume nitrous oxide in the soil. The transformations involve inorganic nitrogen compounds in the soil, namely ammonium, nitrite and nitrate.

Nitrogen compounds can be added to the soil through the following processes:

- a) the application of inorganic nitrogen fertilisers
- b) the application of animal wastes and sewage sludge to pastures
- c) the application of crop residues
- d) mineralisation due to loss of soil carbon
- e) mineralisation due to cultivation of organic soils
- f) atmospheric nitrogen deposition

A further source of nitrous oxide is associated with leaching of N from soils and surface runoff, and subsequent denitrification in rivers and estuaries.

5.6.2 Inorganic fertilisers (3.D.A.1)

A CS method is used to estimate emissions from inorganic fertilisers. The EFs are based on analyses of Australian measurement studies (Scherbak and Grace 2014; Scherbak *et al.* 2014), including those undertaken through programs such as the Nitrous Oxide Research Program (NORP) and the National Agricultural Nitrous Oxide Research Program (NANORP). The work of Scherbak and Grace was reviewed by the Expert Advisory Panel and approved for use in the Australian NIR (see Table 5.4).

This experimental work on the application of fertilisers to different production systems and climatic regions in Australia has shown large variations from the IPCC 2006 default EF of 1 per cent across different classes of crop and pasture systems.

Variation in EFs with region and production system is to be expected. For example, the majority of Australian grain production is from rain-fed cultivation in relatively low rainfall areas where low rates of nitrogen fertiliser inputs, low decomposition rates and low levels of microbial activity (Barton *et al.* 2008) contribute to a lower denitrification potential.

It is also now becoming apparent that the EFs in some production systems increase with nitrogen application rates. For example, Scherbak *et al.* (2014) have developed a two component (linear + exponential) model for cotton which gives EF (per cent) = $0.29 + (0.007(e^{0.037 \cdot \text{N application rate}} - 1)) / \text{N application rate}$.

The EFs used in the inventory for inorganic fertiliser are provided in Table 5.23.

Calculation of fertiliser applied to each production system

Total fertiliser use in each State is provided by Fertilizer Australia. The fraction of fertiliser applied to each production system (FN_{ij}) was determined for each State by first estimating the mass of N-fertiliser applied to irrigated crops, irrigated pasture, cotton, sugar cane and horticulture using the production areas reported by ABS (see Appendix Table 5.H.1) and the average fertiliser application rates for each of these crops. The balance of the fertiliser is then distributed to rain-fed crops and modified pastures (derived from Stewart *et al.* 2001) in proportion to their respective areas.

Fertiliser application rates assigned to irrigated crops, irrigated pastures, cotton, and horticultural crops and vegetables are respectively 80 kg N/ha, 80 kg N/ha, 246 kg N/ha, and 125 kg N/ha. For sugar cane, a variable application rate is used (see Appendix 5.H.2). Sugar cane fertiliser application rates in QLD have declined significantly over the time series in response to environmental management legislation.

Table 5.22 Symbols used in algorithms for inorganic fertiliser

State (i)	Activity (j)
1 = ACT	1 = Irrigated pasture
2 = Northern Territory	2 = Irrigated crop
3 = NSW	3 = Non-irrigated pasture
4 = Queensland	4 = Non-irrigated crop
5 = Tasmania	5 = Sugar cane
6 = South Australia	6 = Cotton
7 = Victoria	7 = Horticulture
8 = Western Australia	

Table 5.23 Nitrous oxide EFs for inorganic fertiliser

Production system	Emission factor ^(a) (Gg N ₂ O-N/ Gg N)
Irrigated pasture	0.0039
Irrigated crop	0.0085
Non-irrigated pasture	0.0021
Non-irrigated crop	0.0020 ^(b)
Sugar cane	0.0199
Cotton	0.0055 ^(c)
Horticulture	0.0085

(a) Based on Scherbak and Grace (2014).

(b) Weighted EF assuming 80 per cent of non-irrigated crops occur on low rainfall areas.
Low rainfall EF = 0.0005 and high rainfall EF = 0.0085.

(c) Based on Scherbak *et al.* (2014) and an N application rate of 246 kg/ha.

Limited amounts of fertiliser are also used in Australian forests. Currently there is no data available to allocate fertiliser use specifically to forestry activities. Given the approach taken to allocating fertiliser, it is assumed that any fertiliser applied for forestry activities will fall under the non-irrigated systems and have an EF of 0.2 per cent applied.

The mass of fertiliser applied to soils via crop production systems (M_{ij} Gg N) is calculated as:

$$M_{ij} = TM_{ij} \times FN_{ij} \quad (3DA_1)$$

Where TM_{ij} = total mass of fertiliser (Gg N)
 FN_{ij} = fraction of N applied to production system J

Annual nitrous oxide production from the addition of organic fertilisers (E_{ij} Gg N_2O) is calculated as:

$$E_{ij} = \sum_i \sum_j (M_{ij} \times EF_{ij} \times C_g) \quad (3DA_2)$$

Where EF_{ij} = emission factor (Gg N_2O -N/Gg N applied) (Table 5.23)
 C_g = 44/28 factor to convert elemental mass of N_2O to molecular mass

5.6.3 Organic fertilisers: Animal wastes applied to soils (3.D.A.2.a)

Direct emissions from organic fertilisers (3.D.A.2) arise from both animal wastes applied to soils (3.D.A.2.a) and sewage sludge applied to land (3.D.A.2.b). Nitrous oxide is emitted from soil through the metabolism of animal manure derived principally from dairies, feedlots, piggeries and poultry houses and applied to crops and pastures as organic fertiliser.

The IPCC (2006) default EF for N_2O emissions from animal wastes applied to soils (1 per cent) is used for dairies, feedlots and poultry houses. Piggeries uses a direct N_2O factor of 0.0039 N_2O -N/Gg N deposited based on the output of the PigBal model (Skerman *et al.* 2013).

Inputs to this subsector are calculated using MMS equations in Section 5.4.

Table 5.24 Symbols used in algorithms for animal wastes applied to soils

State (i)	Activity (j)
1 = ACT	1 = Dairy cattle
2 = Northern Territory	2 = Beef cattle - feedlot
3 = NSW	3 = Swine
4 = Queensland	4 = Poultry
5 = Tasmania	
6 = South Australia	
7 = Victoria	
8 = Western Australia	

The amount of nitrogen applied to soils is the nitrogen excreted, adjusted for the nitrogen that has already been lost as N_2O , NH_3 and NO_x during storage in the different MMS.

Thus the nitrogen content of animal wastes applied to agricultural soils (MN Soil_{ij}) is calculated as:

$$\text{MN Soil}_{ij} = \sum_{\text{MMS}} ((\text{AE}_{ij \text{ MMS}=1-13} \times (1 - \text{EF}_{\text{MMS}=1-13} - \text{FracGASM}_{j \text{ MMS}=1-13})) - \text{MNLEACH}_{ij \text{ MMS}=1-13}) \quad (3\text{DA}_3)$$

Where $\text{AE}_{ij \text{ MMS}=1-13}$ = mass of N excreted, calculated in Section 5.4. For dairy cattle AE_{ij} is the sum of faecal (AF) and urinary (AU) nitrogen

$\text{EF}_{\text{MMS}=1-13}$ = direct nitrous oxide EF from the different MMS (Appendix 5)

$\text{FracGASM}_{j \text{ MMS}=1-13}$ = fraction of animal waste N volatilised from the different MMS (Appendix 5)

$\text{MNLEACH}_{ij \text{ MMS}=1-13}$ = mass of animal waste N from leaching and runoff, calculated in Section 5.4

Annual nitrous oxide production from animal wastes applied to soils (E_{ij} Gg N₂O) is calculated as:

$$E_{ij} = \sum_i \sum_j (\text{MN Soil}_{ij} \times \text{EF} \times C_g) \quad (3\text{DA}_4)$$

Where $\text{EF} = 0.01$ (Gg N₂O-N/Gg N deposited) IPCC 2006

$C_g = 44/28$ factor to convert elemental mass of N₂O to molecular mass

5.6.4 Organic fertilisers: Sewage sludge applied to land (3.D.A.2.b)

Direct emissions from organic fertilisers (3.D.A.2) arise from both animal wastes applied to soils (3.D.A.2.a) and sewage sludge applied to land (3.D.A.2.b). Treated sewage sludge is applied to land in Australia for the purposes of disposal rather than as a fertiliser for agricultural production, due to health concerns. A CS EF based on experimental studies where sewage sludge was applied to soils (Bouwman *et al.* 2002) is used to estimate emissions. The experiments gave an average N₂O EF of 0.9 per cent (range 0.8 to 1.0 per cent).

Activity data is from the *waste* sector (category 5.D wastewater treatment and discharge – domestic and commercial). The quantity of sewage sludge removed from wastewater treatment plants for application to land is reported by wastewater treatment plants under the National Greenhouse and Energy Reporting System (NGERS). See Section 7.6 ‘Waste Wastewater Treatment and Discharge’ in Volume 2 of the NIR for further information.

Table 5.25 Symbols used in algorithms for sewage sludge applied to land

State (i)
1 = ACT
2 = Northern Territory
3 = NSW
4 = Queensland
5 = Tasmania
6 = South Australia
7 = Victoria
8 = Western Australia

Annual nitrous oxide production from sewage sludge applied to land (E_i Gg N₂O) is calculated as:

$$E_i = \sum_i (M_i \times \text{EF} \times C_g) \quad (3\text{DA}_5)$$

Where M_i = Mass of sewage sludge N applied to lands (Gg)

$\text{EF} = 0.009$ (Gg N₂O-N/Gg N) Bouwman *et al.* 2002

$C_g = 44/28$ factor to convert elemental mass of N₂O to molecular mass

5.6.5 Urine and dung deposited by grazing animals (3.D.A.3)

Nitrous oxide is emitted from soil through the metabolism of urine and faeces deposited directly onto pastures.

Urine experiments conducted on rain-fed legumes and annual pastures in central NSW (Galbally *et al.* 1994), and irrigated pastures in Victoria (Galbally *et al.* 2005) found emission rates of 0.4 per cent. There are still relatively few measurements of EFs from animal faeces deposited directly to soil in the absence of urine but Flessa *et al.* (1996), Yamulki and Jarvis (1997), and Oenema *et al.* (1997) have reported emission rates from dung of 0.3–0.7 per cent. As such, an EF of 0.4 per cent (0.004 Gg N₂O-N/Gg N), is used to estimate N₂O emissions from urinary and faecal N deposition to soil. This value is within the uncertainty range for both the IPCC 2006 and IPCC 2019 EF.

Table 5.26 Symbols used in algorithms for urine and dung deposited by grazing animals

State (i)	Activity (j)
1 = ACT	1 = Dairy cattle
2 = Northern Territory	2 = Beef cattle – pasture
3 = NSW	3 = Sheep
4 = Queensland	4 = Poultry
5 = Tasmania	5 = Other livestock
6 = South Australia	
7 = Victoria	
8 = Western Australia	

Annual nitrous oxide production from urine and dung deposited by grazing animals (E_{ij} Gg N₂O) is calculated as:

$$E_{ij} = \sum_i \sum_j ((AF_{ij, \text{MMS}=14} \times EF_j \times C_g) + (AU_{ij, \text{MMS}=14} \times EF_j \times C_g)) \quad (3DA_6)$$

Where $AF_{ij, \text{MMS}=14}$ and $AU_{ij, \text{MMS}=14}$ = mass of faecal and urinary nitrogen excreted on pasture range and paddock as calculated in Section 5.4. For poultry all N excreted is assumed to be faeces

EF_j = 0.004 (Gg N₂O-N/Gg N deposited)

C_g = 44/28 factor to convert elemental mass of N₂O to molecular mass

5.6.6 Crop Residues (3.D.A.4)

The method used to estimate emissions from crop residues returned to the soil is based on the IPCC tier 2 method and EF but using CS crop production activity data. This subsector also includes emissions from pasture residues returned to the soil. The IPCC (2006) default EF for N₂O emissions from crop residues (1 per cent) is used. This value did not change in the IPCC 2019 Refinement.

Table 5.27 Symbols used in algorithms for crop residues

State (i)	Crops (j)	Pasture (k)	Pasture renewal system (l)
1 = ACT	1 = Wheat	1 = Lucerne	1 = Intensive (1 in 10 years)
2 = NT	2 = Barley	2 = Other legume pasture	2 = Other (1 in 30 years)
3 = NSW	3 = Maize	3 = Grass clover mixture	
4 = Qld	4 = Oats	4 = Perennial pasture	
5 = Tas	5 = Rice	5 = Annual grass	
6 = SA	6 = Sorghum		
7 = Vic	7 = Triticale		
8 = WA	8 = Other cereals		
	9 = Pulses		
	10 = Tubers and roots		
	11 = Peanuts		
	12 = Sugar cane		
	13 = Cotton		
	14 = Hops		
	15 = Oilseeds		
	16 = Forage crops		

The mass of N in crop residues returned to soils (M_{ijk} Gg N) is calculated as:

$$M_{ijk} = (P_{ij} \times R_{AGj} \times (1 - F_{ij} - FFOD_{ij}) \times DM_j \times NC_{AGj}) + (P_{ij} \times R_{AGj} \times R_{BGj} \times DM_j \times NC_{BGj}) \dots (3DA_7)$$

- Where
- P_{ij} = annual production of crop (Gg)
 - R_{AGj} = residue to crop ratio (kg crop residue/kg crop) (Appendix 5.1.1)
 - R_{BGj} = below ground-residue to above ground residue ratio (kg /kg) (Appendix 5.1.1)
 - F_{ij} = fraction of crop residue that is burnt (Appendix 5.1.1)
 - $FFOD_{ij}$ = fraction of the crop residue that is removed (Appendix 5.1.1)
 - DM_j = dry matter content (kg dry weight/kg crop residue) (Appendix 5.1.1)
 - NC_{AGj} = nitrogen content of above-ground crop residue (kg N/kg DM) (Appendix 5.1.1)
 - NC_{BGj} = nitrogen content of below-ground crop residue (kg N/kg DM) (Appendix 5.1.1)

The mass of N in pasture residues returned to soils (M_{ikl} Gg N) is calculated as:

$$M_{ikl} = (A_{ikl} \times \text{Frac}_{\text{Renewal}} \times (Y_k / 1000) \times (1 - FFOD_{ik}) \times NC_{AGk}) + (A_{ikl} \times \text{Frac}_{\text{Renewal}} \times (Y_k / 1000) \times R_{BGk} \times NC_{BGk}) \dots (3DA_8)$$

- Where
- A_{ikl} = Area of pasture (ha)
 - $\text{Frac}_{\text{Renewal}}$ = Fraction of pasture renewed = $1/X$ where X is the average renewal period in years: 10 years for intensive systems and 30 years for other systems
 - Y_k = Average yield (t DM/ha) (Appendix 5.1.2)
 - R_{BGk} = below ground-residue:above ground residue ratio (kg /kg) (Appendix 5.1.1)
 - NC_{AGk} = N content of above-ground crop residue (kg N/kg DM) (Appendix 5.1.1)
 - NC_{BGk} = N content of below-ground crop residue (kg N/kg DM) (Appendix 5.1.1)
 - $FFOD_{ik}$ = fraction of pasture yield that is removed (Appendix 5.1.2)

Annual nitrous oxide production from crop residues (E_i Gg N_2O) is calculated as:

$$E_i = \sum_l \sum_k \sum_j (M_{ijkl} \times EF \times C_g) \quad (3DA_9)$$

Where M_{ijkl} = mass of N in crop residues (Gg N)
 EF = 0.01 (Gg N_2O -N/Gg N) IPCC 2006 default
 C_g = 44/28 factor to convert from elemental mass of N_2O to molecular mass

5.6.7 Mineralisation due to loss of soil carbon (3.D.A.5)

Where a loss of soil carbon in *cropland remaining cropland* occurs, this loss will be accompanied by a simultaneous mineralisation of N. This mineralised N is considered as an additional source of N available for conversion to N_2O , along with mineralised N released through the decomposition of crop residues (IPCC 2006). In years in which *cropland remaining cropland* is a net sink there may be no emissions reported in this category.

The IPCC (2006) method, using CS parameters and EFs, is used to calculate N_2O emissions from this source. The C:N value used is 10, reflecting the approximate median value extracted from a survey of national estimates (Snowdon *et al.* 2005).

The CS EF for fertiliser additions to non-irrigated crops is then applied (see Table 5.23). The EF is based on analyses of Australian measurement studies (Scherbak and Grace 2014; Scherbak *et al.* 2014), including those undertaken through programs such as the Nitrous Oxide Research Program (NORP) and the National Agricultural Nitrous Oxide Research Program (NANORP).

The experimental work on the application of fertilisers to different Australian production systems showed large variations from the IPCC default EF of 1 per cent, across different classes of crop and pasture systems. The work of Scherbak and Grace was reviewed by the Expert Advisory Panel and approved for use in the Australian NIR (see Table 5.4).

Table 5.28 Symbols used in algorithms for mineralisation due to loss of soil C

State (i)
1 = ACT
2 = Northern Territory
3 = NSW
4 = Queensland
5 = Tasmania
6 = South Australia
7 = Victoria
8 = Western Australia

Annual nitrous oxide production from mineralisation due to loss of soil carbon (E_j Gg N_2O) is calculated as:

$$E_j = \sum_l (M_l \times NC \times EF \times C_g) \quad (3DA_{10})$$

Where M_l = loss of soil carbon in *cropland remaining cropland* (Gg)
 NC = nitrogen to carbon ratio for cropland soils
 EF = 0.002 (Gg N_2O -N/Gg N) Scherbak and Grace 2014
 C_g = 44/28 factor to convert elemental mass of N_2O to molecular mass

5.6.8 Cultivation of histosols (3.D.A.6)

The default IPCC tier 1 methodology is used to estimate emissions from the cultivation of histosols.

The area of cultivated histosols is very limited in Australia (known as organosols in the Australian Soil Classification 2016). Organosols occur in Queensland where they are mostly used for sugar cane production, and small locations in Victoria where peatlands were cleared and subsequently grazed or cropped. Individual patches are typically very small, which leads to significant uncertainty when estimating the national area. The land area for histosols was estimated using expert judgement (C. Meyer pers. comm.). There is also a large area of histosols in Tasmania, although this land is not cultivated, so is not included in Australia's calculations for cultivation of histosols.

The area of cultivated histosols used in the estimation of emissions from cultivated organic soils, is crosschecked with those reported in the LULUCF sector to ensure consistency.

The EF used takes into account the different climatic conditions associated with the two isolated areas. A weighted average of 14 is applied, calculated from a factor of 16 for Queensland, for tropical organic crop and grassland soils, and 8 for Victoria, for temperate organic crop and grassland soils (IPCC 2006).

Table 5.29 Symbols used in algorithms for cultivation of histosols

State (i)
1 = ACT
2 = Northern Territory
3 = NSW
4 = Queensland
5 = Tasmania
6 = South Australia
7 = Victoria
8 = Western Australia

Annual nitrous oxide production from cultivation of histosols (E_i Gg N_2O) is calculated as:

$$E_i = \sum_i (A_i \times EF \times C_g \times 10^{-6}) \quad (3DA_{11})$$

Where A_i = area of cultivated histosols (ha)
 EF = 14 kg N_2O -N/ha (weighted average of IPCC 2006 default values)
 C = 44/28 factor to convert elemental mass of N O to molecular mass

5.6.9 Atmospheric deposition (3.D.B.1)

A CS method is used to estimate indirect emissions for atmospheric N_2O deposition from inorganic fertilisers, manure and sewage sludge. As the highest deposition rates (kg/ha) are found within a few hundred meters of the emission source, the EFs applied for deposition are related to the source of N.

For N volatilised from inorganic fertilisers or sewage sludge, the CS EFs applied for atmospheric deposition are the same as those applied for direct N_2O emissions (see Table 5.25). The EFs are based on analyses of Australian measurement studies (Scherbak and Grace 2014; Scherbak *et al.* 2014), including those undertaken through programs such as the Nitrous Oxide Research Program (NORP) and the National Agricultural Nitrous Oxide Research Program (NANORP). This experimental work showed large variations from the IPCC default EF of 1 per cent across different types of crop and pasture systems. The work of Scherbak and Grace was reviewed by the Expert Advisory Panel and approved for use in the Australian NIR (see Table 5.4).

For N derived from a manure source, the inorganic fertiliser EF which best represents the production system immediately surrounding the farm is used to estimate atmospheric deposition emissions.

Country specific FracGASMsoil and FracGASF values are used to calculate N volatilised from organic and synthetic fertilisers, and animal waste deposited on soils. They are based on syntheses of the latest internationally-assessed science, as reported in IPCC (2019). The *2019 Refinement to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories* (IPCC 2019) informed improvements to Australia's country-specific emission estimation approaches consistent with decision 24/CP.19 (Annex I.E, para 10, *Revision of the UNFCCC reporting guidelines on annual inventories for Parties included in Annex I to the Convention*). The reported uncertainty range for the revised values have narrowed (IPCC 2019), indicating better accuracy than the previous IPCC 2006 default value.

Table 5.30 Symbols used in algorithms for atmospheric deposition

State (i)	Activity (j)
1 = ACT	1 = Inorganic fertiliser
2 = Northern Territory	2 = Manure
3 = NSW	3 = Sewage sludge applied to land
4 = Queensland	
5 = Tasmania	
6 = South Australia	
7 = Victoria	
8 = Western Australia	

The mass of N volatilised from inorganic fertiliser applied to soils ($M_{ij=1}$ Gg N) is calculated as:

$$M_{ij=1} = TM_{ij=1} \times \text{FracGASF}_j \quad \text{(3DB_1)}$$

Where $TM_{ij=1}$ = total mass of fertiliser (Gg N), estimated in Section 5.6.2
 $\text{FracGASF}_j = 0.11$ (Gg N/Gg applied) (CS EF, source IPCC (2019))

The mass of N volatilised from animal waste deposited on or applied to soils ($M_{ij=2}$ Gg N) is calculated as:

$$M_{ij=2} = \Sigma (\text{MNsoil}_{ij} + \text{UNsoil}_{ij} + \text{FNsoil}_{ij}) \times \text{FracGASMsoil}_{ij} \quad \text{(3DB_2)}$$

Where MNsoil_{ij} = mass of manure N applied to soils (Gg N)
 UNsoil_{ij} = mass of urinary N excretion on pasture (Gg N)
 FNsoil_{ij} = mass of faecal N excretion on pasture (Gg N)
 $\text{FracGASMsoil}_{ij} = 0.21$ (kg $\text{NH}_3\text{-N} + \text{NOx-N}$) (kg N applied or deposited)⁻¹ (CS EF, source IPCC (2019))

The mass of N volatilised from sewage sludge applied to soils ($M_{ij=3}$ Gg N) is calculated as:

$$M_{ij=3} = TM_{ij=3} \times \text{FracGASS}_j \quad \text{(3DB_3)}$$

Where $TM_{ij=3}$ = total mass of sewage sludge (Gg N)
 $\text{FracGASS}_j = 0.21$ (Gg N/Gg applied) (CS EF, source IPCC (2019))

Annual nitrous oxide production from atmospheric deposition (E Gg N_2O) is calculated as:

$$E = \Sigma_i \Sigma_j (M_{ij} \times \text{EF}_{ij} \times C_g) \quad \text{(3DB_4)}$$

Where M_{ij} = mass of N volatilised from each sub-sector (Gg N)
 EF_{ij} = source specific EF (Gg $\text{N}_2\text{O-N}$ /Gg N)
 $C_g = 44/28$ factor to convert elemental mass of N_2O to molecular mass

5.6.10 Leaching and runoff (3.D.B.2)

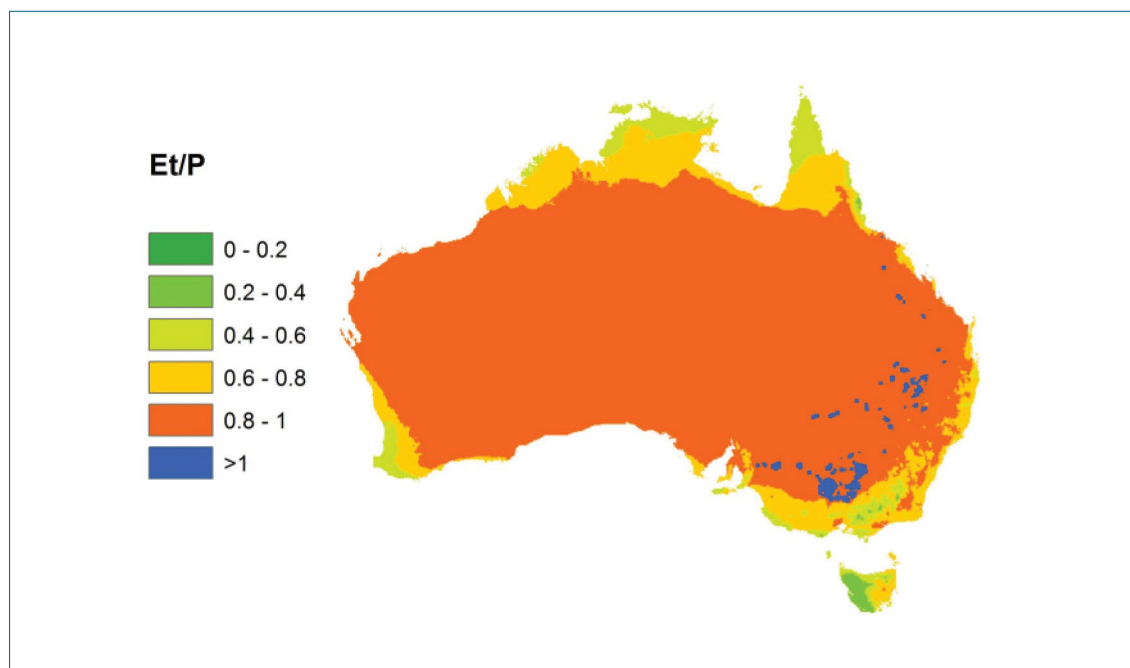

Australia is the driest continent, with substantially less runoff than all other continents. In Australia, much of the cropping takes place in semi-arid regions, or regions of marginal rainfall. Leaching of applied nitrogen into waterways and estuaries is unlikely where evaporation exceeds precipitation (IPCC 2019).

Areas in Australia which are unlikely to be susceptible to significant leaching can be identified using the ratio of evapotranspiration to annual precipitation (Et/P). Evapotranspiration is a better measure than evaporation as it takes into account climatic factors (rainfall, humidity, temperature, wind speed) as well as the effect of different vegetation types (forest, shrubland, grassland) on the demand for soil water.

Evapotranspiration has been estimated using the biogeochemical model BIOS (Raupach *et al.* 2000) for the National Land and Water Audit. Et/P ranges up to 1 where all rainfall is returned to the atmosphere. In areas such as wetlands and irrigation areas in inland regions, where water supply additional to precipitation is available, Et/P can exceed 1.

In this methodology, we consider leaching to occur where $Et/P < 0.8$ or $Et/P > 1$ (Figure 5.5). Regions outside these areas are considered to be 'dryland' and not subject to leaching. The fraction of each crop and animal class occurring outside the dryland areas (FracWET) were determined by overlaying the dryland area mask onto the spatial map of crops, pastures and animal density from the 1997 Agricultural census (ABS 1999).

Figure 5.5 The ratio of mean annual evapotranspiration to annual precipitation (Et/P)

Indirect emissions from leaching and runoff arise from five sources:

- Inorganic fertiliser
- Animal wastes applied to soils
- Sewage sludge applied to land
- Crop residues
- Mineralisation due to loss of soil C

A CS FracLEACH value and a CS N₂O EF are used to calculate N that is lost through leaching and runoff, based on the latest internationally-assessed science, as reported in IPCC (2019). The *2019 Refinement to the 2006 IPCC Guidelines for National Greenhouse Gas Inventories* (IPCC 2019) informed improvements to Australia's country-specific emission estimation approaches consistent with decision 24/CP.19 (Annex I.E, para 10, *Revision of the UNFCCC reporting guidelines on annual inventories for Parties included in Annex I to the Convention*).

Consistent with decision 24/CP.19 (Annex I.E, para 10), these country-specific approaches draw on the IPCC 2019 to the extent they are better able to reflect Australia's situation than the IPCC 2006. The introduction of the new estimation approaches has improved the accuracy and completeness of Australia's inventory.

Table 5.31 Symbols used in algorithms for leaching and runoff

State (i)	Activity (j)
1 = ACT	1 = Inorganic fertiliser
2 = Northern Territory	2 = Animal waste
3 = NSW	3 = Sewage sludge
4 = Queensland	4 = Crop residues
5 = Tasmania	5 = Mineralisation due to loss of soil C
6 = South Australia	
7 = Victoria	
8 = Western Australia	

The mass of inorganic fertiliser N applied to soils that is lost through leaching and runoff ($M_{ij=1}$ Gg N) is calculated as:

$$M_{ij=1} = M_{ij} \times \text{FracWET}_{ij} \times \text{FracLEACH} \quad \text{(3DB_5)}$$

Where M_{ij} = mass of fertiliser in each production system (Gg N), calculated in Section 5.6.2.
 FracWET_{ij} = fraction of N available for leaching and runoff (Appendix 5.J.1)
 FracLEACH = 0.24 (Gg N/Gg applied) (CS EF, source IPCC (2019))

The mass of animal waste N excreted or applied to soil that is lost through leaching and runoff ($M_{ij=2}$ Gg N) is calculated as:

$$M_{ij=2} = (\text{MNsoil}_{ij} + \text{UNsoil}_{ij} + \text{FNsoil}_{ij}) \times \text{FracWET}_{\text{soilij}} \times \text{FracLEACH} \quad \text{(3DB_6)}$$

Where MNsoil_{ij} = mass of manure N applied to soils (Gg N), calculated in Section 5.6.3
 UNsoil_{ij} = mass of urinary N excretion on pasture (Gg N), calculated in Section 5.6.9
 FNsoil_{ij} = mass of faecal N excretion on pasture (Gg N), calculated in Section 5.6.9
 $\text{FracWET}_{\text{soilij}}$ = fraction of N available for leaching and runoff (Appendix 5.J.2)
 FracLEACH = 0.24 (Gg N/Gg applied) (CS EF, source IPCC (2019))

The mass of sewage sludge N applied to soils that is lost through leaching and runoff ($M_{ij=3}$ Gg N) is calculated as:

$$M_{ij=3} = M_{ij} \times \text{FracWET}_{ij} \times \text{FracLEACH} \quad \text{(3DB_7)}$$

Where M_{ij} = mass of sewage sludge N (Gg N), calculated in Section 5.6.4
 FracWET_{ij} = fraction of N available for leaching and runoff = 1.0
 FracLEACH = 0.24 (Gg N/Gg applied) (CS EF, source IPCC (2019))

The mass of crop residue that is lost through leaching and runoff ($M_{ij=4}$ Gg N) is calculated as:

$$M_{ij=4} = M_{ij} \times \text{FracWET}_{ij} \times \text{FracLEACH} \quad \text{(3DB_8)}$$

Where M_{ij} = mass of crop residue N (Gg N), calculated in Section 5.6.6
 FracWET_{ij} = fraction of N available for leaching and runoff (Appendix 5.J.1)
 FracLEACH = 0.24 (Gg N/Gg applied) (CS EF, source IPCC (2019))

The mass of N mineralised due to a loss of soil C lost through leaching and runoff ($M_{ij=5}$ Gg N) is calculated as:

$$M_{ij=5} = M_{ij} \times \text{FracWET}_{ij} \times \text{FracLEACH} \quad \text{(3DB_9)}$$

Where M_{ij} = mass of N mineralised due to a loss of soil C (Gg N)
 FracWET_{ij} = fraction of N available for leaching and runoff (Appendix 5.J.1 – non-irrigated crops)
 FracLEACH = 0.24 (Gg N/Gg applied) (CS EF, source IPCC (2019))

Annual nitrous oxide production from leaching and runoff (E Gg N_2O) is calculated as:

$$E = \sum_j (M_{ij} \times \text{EF} \times C_g) \quad \text{(3DB_10)}$$

Where M_{ij} = mass of N lost through leaching and runoff (Gg N)
 EF = 0.011 (Gg N_2O -N/Gg N) (CS EF, source IPCC 2019)
 C_g = 44/28 factor to convert elemental mass of N_2O to molecular mass

5.6.11 Uncertainties and time series consistency

A quantitative assessment of uncertainty was undertaken and uncertainties for agricultural soils were estimated to be in the order of 56 per cent. Further details on the analysis are provided in Annex 2.

Time series consistency is ensured by the use of consistent methods and full time series recalculations for all refinements to methodology. See section 5.2.1 regarding how changes to data collection methods by the Australian Bureau of Statistics have been addressed to ensure time series consistency of livestock numbers, and reasons for differences in beef cattle and poultry populations with published FAO data.

5.6.12 Source specific QA/QC

5.6.12.1 Quality control

The Australian Bureau of Statistics (ABS) is the national statistical agency of Australia and is the key provider of activity data for this source category. ABS has in place a range of quality assurance-quality control procedures associated with survey design, data input and consistency checks on the survey results and the aggregated values. Sampling errors are also evaluated. Data quality used in the inventory is also kept under review by the DISER.

This source category is also covered by the general QA/QC procedures detailed in Chapter 1. The QC procedure ‘ensuring consistency in data between categories’ is of specific importance for this category. The AGEIS ensures that data used across multiple categories is entered only once and that intakes or emissions calculated in one category form the input for other categories.

Fertilizer Australia is the industry association representing manufacturers, importers and distributors of fertiliser in Australia. The FAO receives their data from the International Fertilizer Association (IFA), which originates from Fertilizer Australia (Fertilizer Australia provides data to IFA, which they share with FAO).

Inorganic N consumption data supplied by Fertilizer Australia and used in the inventory is compared with data published by the FAO. The results are very close between the two data sources (typically less than 1 per cent) throughout the time-series.

DISER fertiliser use data differs slightly to FAO's data throughout the available FAO time-series. There are two main reasons which account for these observed differences:

- The FAO rounds their published data to the nearest '000 tonnes, while Australia uses fertiliser data to the nearest tonne;
- Fertilizer Australia revises their data frequently to ensure accuracy. In a number of years revisions have occurred between the provision of data to IFA and to DISER. These revisions are not reflected in the FAO data.

5.6.12.2 Quality assurance

As data from additional research into fertiliser EFs are published, the results are used to QA the selected CS EFs. Where new studies give values that are significantly different from the CS EFs, these EFs are identified for review.

5.6.13 Recalculations since the 2019 Inventory

Recalculations of *agricultural soils* estimates have occurred in the 2022 submission due to:

- The application of the default factors for the parameters FracLEACH-H (fraction of N lost through leaching and runoff in managed soils) and FracLEACH-MS (fraction of managed manure N losses) from the 2019 Refinement to the 2006 IPCC Guidelines, according to ERT recommendation A.3.

Table 5.32 shows the impacts of recalculations.

Table 5.32 Agricultural soils (3.D): recalculations of total CO₂-e emissions, 1990–2019

Year	2021 submission	2022 submission	Change	
	(Gg CO ₂ -e)	(Gg CO ₂ -e)	(Gg CO ₂ -e)	(per cent)
1990	12,343	12,426	83	0.7
2000	13,327	13,338	11	0.1
2005	12,949	12,983	34	0.3
2010	11,546	11,573	26	0.2
2011	12,702	12,732	31	0.2
2012	13,164	13,193	29	0.2
2013	12,964	12,987	23	0.2
2014	13,540	13,572	32	0.2
2015	12,939	12,959	20	0.2
2016	13,063	13,082	19	0.1
2017	14,590	14,606	16	0.1
2018	13,370	13,384	14	0.1
2019	12,210	12,229	20	0.2

5.6.14 Source specific planned improvements

The inventory improvement plan for the agriculture sector identified areas which require updating or review over the next few years. Areas for improvement are identified through the UNFCCC expert reviews, domestic QA/QC processes or the expected availability of new data or empirical studies which could improve accuracy of the inventory.

For agricultural soils the following areas have been identified for review and/or change:

1. Work towards phased transition of emissions estimation methods to more complex IPCC tier 3 methods for some elements of the agricultural soils subsector.
2. In response to an ERT recommendation, use the most recent published information to locate source data to provide information on how inorganic fertiliser EFs are weighted by crop type, climate region, management system and fertiliser type.
3. Consider the disaggregation of inorganic fertiliser EFs into urea and non-urea fertiliser EFs in response to an ERT recommendation.
4. Investigate the application of N₂O EFs for crop residues that are specific to the climate zones crops are produced in, instead of using a single default EF.

5.7 Source Category 3.E Prescribed Burning of Savannas

Non-CO₂ emissions from prescribed burning of savannas has been reallocated to 4.A.1 *Forestland remaining forestland*, 4.C.1 *Grassland remaining grassland* and 4.C.2 *Land converted to grassland* to align Australia's reporting with the categories specified in the 2006 IPCC Guidelines (which do not mention savanna burning).

Refer to Volume 2 of the NIR for further information about the methods used to estimate emissions from prescribed burning of savannas.

This change is a classification of emissions issue only, and does not change the national inventory total.

5.8 Source Category 3.F Field Burning of Agricultural Residues

5.8.1 Source category description and methodology

The burning of residual crop material releases CH₄, N₂O, CO, NO_x and NMVOCs into the atmosphere.

These gases are formed from carbon and nitrogen in the plant material during the combustion process. As per the IPCC *Guidelines* (IPCC 2006), the CO₂ emissions from burning of agricultural residues are not included in the inventory total since it is assumed that an equivalent amount of CO₂ was removed by the growing crop. However emissions from the other gases are included in the inventory.

Stubble burning involves firing the standing stalks in either late autumn or spring. Increasingly, this form of land management is being replaced by stubble retention, which reduces erosion and conserves nutrients. In this latter practice the stubble is grazed some weeks after harvest and the next crop is sown by drilling through the remaining vegetation. Firing of sugar cane has also become less common with the rapid introduction of green cane mechanical harvesting. Sugar cane crops are now burnt once every three or four years at the end of the sowing/ratoon cycle.

The amount of crop residue at the time of burning is in most cases, less than that at the time of harvest. This applies particularly to crops where there is a long interval between harvest and burning. Vegetation decay and grazing by animals can, over several months, reduce the amount of residue per unit area by one half (R. Jarvis pers. comm., Mulholland *et al.* 1976). This loss is allowed for in the algorithm.

Table 5.33 Burning of agricultural residues – EFs

Gas species	Emission factor EF_g (Gg element in species/ Gg element in fuel burnt)	Elemental to molecular mass conversion factor (C_g)
CH ₄	0.0035	16/12
N ₂ O	0.0076	44/28
NO _x	0.2100	46/14
CO	0.0780	28/12
NM VOC	0.0091	14/12

Source: Hurst *et al.* (1994), Hurst and Cook (1994).

Table 5.34 Symbols used in algorithms for burning of agricultural residues

State (i)	Subset (j)
1 = ACT	1 = Wheat
2 = Northern Territory	2 = Barley
3 = NSW	3 = Maize
4 = Queensland	4 = Oats
5 = Tasmania	5 = Rice
6 = South Australia	6 = Sorghum
7 = Victoria	7 = Triticale
8 = Western Australia	8 = Other cereals
9 = Pulses	
10 = Tubers and roots	
11 = Peanuts	
12 = Sugar cane	
13 = Cotton	
14 = Hops	
15 = Oilseeds	
16 = Forage crops	

The mass of residue burnt (M_{ij} Gg) is calculated as:

$$M_{ij} = P_{ij} \times R_j \times S_j \times DM_j \times Z \times F_{ij} \quad (3F_1)$$

Where P_{ij} = annual production of crop (Gg)
 R_j = residue:crop ratio (kg crop residue/kg crop) (Appendix 5.1.1)
 S_j = fraction of crop residue remaining at burning (Appendix 5.1.1)
 DM_j = dry matter content (kg dry weight/kg crop residue) (Appendix 5.1.1)
 Z = burning efficiency (fuel burnt/fuel load) = 0.96 (Hurst *et al.* 1994; Hurst and Cook, 1994)
 F_{ij} = fraction of the annual production of crop that is burnt (ha burnt/ ha harvested) (Appendix 5.1.1 and 5.1.3)

The mass of fuel burnt is converted to emissions of CH_4 , CO or NMVOC by multiplying by the carbon content of the fuel, and an EF:

$$E_{ij} = M_{ij} \times CC_j \times EF_g \times C_g \quad (3F_2)$$

Where E_{ij} = annual emissions from burning of crop residue (Gg)
 CC_j = carbon mass fraction in crop residue (Appendix 5.1.1)
 EF_g = emission factor (Gg element /Gg burnt) (Table 5.33)
 C_g = factor to convert from elemental mass of gas to molecular mass (Table 5.33)

For N_2O and NO_x an additional term in the algorithm, the nitrogen to carbon ratio (NC), is required in order to calculate the fuel nitrogen content. Hence:

$$E_{ij} = M_{ij} \times NC_j \times EF_g \times C_g \quad (3F_3)$$

Where E_{ij} = annual emissions from burning of crop residue (Gg)
 NC_j = nitrogen content in above ground residue (Appendix 5.1.1)
 EF_g = emission factor (Gg element /Gg burnt) (Table 5.33)
 C_g = factor to convert from elemental mass of gas to molecular mass (Table 5.33)

5.8.2 Uncertainties and time series consistency

A quantitative assessment of uncertainty was undertaken and uncertainties for the burning of agricultural residues were estimated to be in the order of 60 per cent. Further details on the analysis are provided in Annex 2. Time series consistency is ensured by the use of consistent methods and full time series recalculations for all refinements to methodology.

5.8.3 Source specific QA/QC

ABS, the principal data supplier, has in place a range of quality assurance-quality control procedures associated with survey design, data input and consistency checks on the survey results and the aggregated values. Sampling errors are also evaluated. Data quality used in the inventory is also kept under review by the Department.

This source category is also covered by the general QA/QC procedures detailed in Chapter 1.

5.8.4 Recalculations since the 2019 Inventory

There were no recalculations to *Field Burning of Agricultural Residues* in the 2022 submission.

5.8.5 Source specific planned improvements

All data and methodologies are kept under review.

5.9 Source Category 3.G Liming

5.9.1 Source category description and methodology

Limestone and dolomite are used in Australia to ameliorate soil acidity, improve soil structure, and improve plant growth in *cropland* and *grassland* and, to a very limited degree, in *forestland*. Adding carbonates to soils in the form of lime (eg. calcic limestone (CaCO_3) or dolomite ($\text{CaMg}(\text{CO}_3)_2$)) results in CO_2 emissions, as the carbonate reacts with acids in the soil to produce bicarbonate and eventually leading to the production of CO_2 and water.

Table 5.35 Symbols used in algorithms for liming

State (i)	Subset (j)
1 = ACT	1 = Limestone
2 = Northern Territory	2 = Dolomite
3 = NSW	
4 = Queensland	
5 = Tasmania	
6 = South Australia	
7 = Victoria	
8 = Western Australia	

For lime application, the annual emissions of CO_2 (E_{ij} Gg) are calculated as:

$$E_{ij} = ((M_{ij} \times \text{FracLime}_{ij} \times P_{j=1} \times \text{EF}_{j=1}) + (M_{ij} \times (1 - \text{FracLime}_{ij}) \times P_{j=2} \times \text{EF}_{j=2})) \times C_g / 1000 \quad (3G_1)$$

Where M_{ij} = mass of limestone and dolomite applied to soils (tonne)

FracLime_{ij} = fraction of lime as limestone or dolomite, derived from the ABS report "Land Management and Farming in Australia". The values of FracLime_{ij} for each State and year are provided in Appendix 5.K.

$P_{j=1}$ = fractional purity of limestone = 0.9 (DCC 2006)

$P_{j=2}$ = fractional purity of dolomite = 0.95 (DCC 2006)

$\text{EF}_{j=1}$ = 0.12 (tonne C/tonne limestone) - IPCC (2006) default emission factor for limestone

$\text{EF}_{j=2}$ = 0.13 (tonne C/tonne dolomite) - IPCC (2006) default emission factor for dolomite

C_g = 44/12 factor to convert elemental mass of CO_2 to molecular mass

5.9.2 Uncertainties and time series consistency

A quantitative assessment of uncertainty was undertaken and uncertainties for liming were estimated to be in the order of 54 per cent. Further details on the analysis are provided in Annex 2.

National data on limestone and dolomite application to agricultural soils are only available from the Australian Bureau of Statistics for eight years (1993, 1994, 1996, 2001, 2002, 2008, 2013 and 2014), with limestone and dolomite reported separately for the following years: 1996, 2001, 2002, 2008, 2013, 2015, 2016 and 2017. As no data have been reported since 2017, the values have been held constant. Investigation of an extrapolation method is a planned improvement.

Additional data is available for Western Australia (1991, 1995, 1998–2000 and 2004). Interpolation techniques were used to estimate the mass of limestone and dolomite applied in years for which data are not available. The fraction of the estimated mass applied that is assumed to be limestone was based on the average of years for which data are available.

5.9.3 Source specific QA/QC

This source category is covered by the general QA/QC procedures detailed in Chapter 1.

5.9.4 Recalculations since the 2019 Inventory

There were no recalculations affecting this subsector in the 2022 submission.

5.9.5 Source specific planned improvements

All data and methodologies are kept under review.

As the ABS have not updated the report of limestone and dolomite application to agricultural soils since 2017, alternative methods of extrapolating the activity data will be investigated.

5.10 Source Category 3.H Urea Application

5.10.1 Source category description and methodology

Adding urea to soils for fertilisation leads to a loss of the CO₂ that was fixed during the manufacturing process. Similar to the reaction following the addition of lime, the bicarbonate that is formed evolves into CO₂ and water.

For urea application, the annual emissions of CO₂ (E_i Gg) are calculated as:

$$E_i = M_i \times EF \times C_g / 1000 \quad (3H_1)$$

Where M_i = mass of urea applied to soils (tonne)

EF = 0.2 (tonne C/tonne urea) – IPCC (2006) default EF for urea

C_g = 44/12 factor to convert elemental mass of CO to molecular mass

5.10.2 Uncertainties and time series consistency

A quantitative assessment of uncertainty was undertaken and uncertainties for application of urea were estimated to be in the order of 51 per cent. Further details on the analysis are provided in Annex 2. Time series consistency is ensured by the use of the same methods and data source for the full time series.

5.10.3 Source specific QA/QC

This source category is covered by the general QA/QC procedures detailed in Chapter 1.

5.10.4 Recalculations since the 2019 Inventory

There were no recalculations affecting this subsector in the 2022 submission.

5.10.5 Source specific planned improvements

All data and methodologies are kept under review.

Note: Integrated factors are derived from the allocation of waste to different MMS (Table 5.C.4) and the specific MCF (Table 5.C.5), N₂O EF (Table 5.C.6) and FracGASMMMS (Table 5.C.7) of each MMS.

Table 5.C.4 Feedlot cattle – Allocation of waste to MMS (per cent)

MMS	1990–1994	1995–1999	2000–2004	2005–2009	2010–2014	2015–2020
Primary Systems						
Drylot (Feedpad)	100.0	100.0	100.0	100.0	100.0	100.0
Secondary Systems^(a)						
Stockpile (Solid storage)	92.0	92.0	77.0	54.0	54.0	54.0
Composting (Passive windrow)	0.0	0.0	15.0	38.0	38.0	38.0
Direct Application	8.0	8.0	8.0	8.0	8.0	8.0
Tertiary System^(b)						
Uncovered anaerobic lagoon (Effluent pond)	2.0	2.0	2.0	2.0	2.0	2.0

(a) 50 per cent of VS is assumed to be lost during storage in the primary system, predominantly as biogenic CO₂ (McGahan *et al.* 2004; Wiedemann *et al.* 2014).

(b) 2 per cent of VS and N from the feed pad is assumed to run-off into effluent ponds (Watts *et al.* 2012, Wiedemann *et al.* 2014).

Appendix 5.E Swine

PIGBAL (v4; Skerman *et al.* 2013) is a nutrient balance model for intensive piggeries in Australia. By entering typical animal characteristics, intakes, diet compositions and wastage rates (Tables 5.E.1 and 5.E.2), the model calculates the volatile solids in animal manure and waste feed and the nitrogen retained by the animals (Table 5.E.3). Swine industry experts provided information such as average intakes for a typical herd.

The model itself is an Excel -based modelling tool available at <https://australianpork.com.au/environmental-practices/waste-management-pigbal>. Supporting documentation is also available from this site.

Source: Wiedemann *et al.* (2014)

- (a) Secondary MMS for waste from deep litter is solid storage. 5 per cent of VS is assumed to be lost in the primary system (Wiedemann *et al.* 2014).
- (b) Secondary MMS for waste from covered pond/digester is an uncovered lagoon. 75 per cent of VS is assumed to be lost in the primary system (Wiedemann *et al.* 2014).
- (c) Separated solids pass directly to the secondary MMS – solid storage.
